Steel Design

Notation:

= name for width dimension D = shorthand for dead load a \boldsymbol{A} = name for area DL= shorthand for dead load = area of a bolt = eccentricity A_h e= effective net area found from the \boldsymbol{E} = shorthand for earthquake load A_e = modulus of elasticity product of the net area A_n by the shear lag factor U = axial compressive stress f_c = gross area, equal to the total area = bending stress f_b A_g ignoring any holes f_p = bearing stress = gross area subjected to shear for = shear stress A_{gv} block shear rupture f_{v-max} = maximum shear stress = net area, equal to the gross area = vield stress A_n f_{v} subtracting any holes, as is A_{net} \boldsymbol{F} = shorthand for fluid load = net area subjected to tension for $F_{allow(able)}$ = allowable stress A_{nt} block shear rupture = allowable axial (compressive) stress F_a = net area subjected to shear for block = allowable bending stress F_h A_{nv} shear rupture = flexural buckling stress F_{cr} = area of the web of a wide flange F_e = elastic critical buckling stress A_w F_{EXX} = yield strength of weld material section AISC = American Institute of Steel = nominal strength in LRFD F_n Construction = nominal tension or shear strength of ASD = allowable stress design a bolt = name for a (base) width = allowable bearing stress F_p = total width of material at a F_t = allowable tensile stress horizontal section F_u = ultimate stress prior to failure = name for height dimension F_{ν} = allowable shear stress = width of the flange of a steel beam = yield strength $F_{\rm v}$ b_f cross section F_{yw} = yield strength of web material = factor for determining M_u for = factor of safety B_1 F.S.combined bending and compression = gage spacing of staggered bolt g = largest distance from the neutral holes caxis to the top or bottom edge of a G= relative stiffness of columns to beams in a rigid connection, as is Ψ = coefficient for shear stress for a h = name for a height c_1 rectangular bar in torsion = height of the web of a wide flange h_c = modification factor for moment in C_{h} steel section ASD & LRFD steel beam design Η = shorthand for lateral pressure load = column slenderness classification C_c Ι = moment of inertia with respect to constant for steel column design neutral axis bending C_m = modification factor accounting for = moment of inertia of trial section I_{trial} combined stress in steel design $I_{req'd}$ = moment of inertia required at C_{v} = web shear coefficient limiting deflection = calculus symbol for differentiation = moment of inertia about the y axis I_{y}

= polar moment of inertia

= depth of a wide flange section

nominal bolt diameternominal bolt diameter

 d_{b}

k = distance from outer face of W flange to the web toe of fillet

= shape factor for plastic design of steel beams

K = effective length factor for columns, as is k

l = name for length

 ℓ_b = length of beam in rigid joint

 ℓ_c = length of column in rigid joint

L = name for length or span length

= shorthand for live load

 L_b = unbraced length of a steel beam

L_c = clear distance between the edge of a hole and edge of next hole or edge of the connected steel plate in the direction of the load

 L_e = effective length that can buckle for column design, as is ℓ_e

 L_r = shorthand for live roof load

 maximum unbraced length of a steel beam in LRFD design for inelastic lateral-torsional buckling

L_p = maximum unbraced length of a steel beam in LRFD design for full plastic flexural strength

L' = length of an angle in a connector with staggered holes

LL = shorthand for live load

LRFD = load and resistance factor design

M = internal bending moment

 M_a = required bending moment (ASD)

 M_n = nominal flexure strength with the full section at the yield stress for LRFD beam design

 M_{max} = maximum internal bending moment

 $M_{max-adj}$ = maximum bending moment adjusted to include self weight

 M_p = internal bending moment when all fibers in a cross section reach the yield stress

 M_u = maximum moment from factored loads for LRFD beam design

 M_y = internal bending moment when the extreme fibers in a cross section reach the yield stress

n = number of bolts

n.a. = shorthand for neutral axis

N = bearing length on a wide flange steel section

= bearing type connection with threads included in shear plane

p = bolt hole spacing (pitch)

P = name for load or axial force vector

 P_a = allowable axial force

= required axial force (ASD)

 $P_{allowable}$ = allowable axial force P_{c} = available axial strength

 P_{el} = Euler buckling strength

 P_n = nominal column load capacity in LRFD steel design

 P_r = required axial force

P_u = factored column load calculated from load factors in LRFD steel design

Q = first moment area about a neutral axis

generic axial load quantity for LRFD design

r = radius of gyration

 r_y = radius of gyration with respect to a y-axis

R = generic load quantity (force, shear, moment, etc.) for LRFD design

= shorthand for rain or ice load

= radius of curvature of a deformed beam

 R_a = required strength (ASD)

 R_n = nominal value (capacity) to be multiplied by ϕ in LRFD and divided by the safety factor Ω in ASD

R_u = factored design value for LRFD design

s = longitudinal center-to-center spacing of any two consecutive holes

S = shorthand for snow load

= section modulus

 allowable strength per length of a weld for a given size

 $S_{req'd}$ = section modulus required at allowable stress

 $S_{req'd-adj}$ = section modulus required at allowable stress when moment is adjusted to include self weight

SC = slip critical bolted connection

= thickness of the connected material = vertical distance y = thickness of flange of wide flange Z= plastic section modulus of a steel t_f = thickness of web of wide flange beam t_w T= torque (axial moment) Z_{x} = plastic section modulus of a steel = shorthand for thermal load beam with respect to the x axis = throat size of a weld Δ_{actual} = actual beam deflection U= shear lag factor for steel tension $\Delta_{allowable}$ = allowable beam deflection member design Δ_{limit} = allowable beam deflection limit = reduction coefficient for block U_{bs} Δ_{max} = maximum beam deflection shear rupture = yield strain (no units) V= internal shear force = resistance factor φ = required shear (ASD) = diameter symbol V_{max} = maximum internal shear force = resistance factor for bending for $\phi_{\scriptscriptstyle b}$ $V_{max-adj} = \text{maximum internal shear force}$ **LRFD** adjusted to include self weight = nominal shear strength capacity for V_n = resistance factor for compression ϕ_c LRFD beam design for LRFD = maximum shear from factored loads V_u = resistance factor for tension for ϕ_{t} for LRFD beam design **LRFD** = name for distributed load = resistance factor for shear for ϕ_{v} $w_{adjusted}$ = adjusted distributed load for **LRFD** equivalent live load deflection limit = load factor in LRFD design $w_{equivalent}$ = the equivalent distributed load γ derived from the maximum bending $= pi (3.1415 \text{ radians or } 180^{\circ})$ π moment θ = slope of the beam deflection curve $w_{self wt}$ = name for distributed load from self = radial distance ρ weight of member Ω = safety factor for ASD W= shorthand for wind load = symbol for integration = horizontal distance х Σ = summation symbol X = bearing type connection with threads excluded from the shear plane

Steel Design

Structural design standards for steel are established by the *Manual of Steel Construction* published by the American Institute of Steel Construction, and uses **Allowable Stress Design** and **Load and Factor Resistance Design**. With the 13th edition, both methods are combined in one volume which provides common requirements for analyses and design and requires the application of the same set of specifications.

Materials

American Society for Testing Materials (ASTM) is the organization responsible for material and other standards related to manufacturing. Materials meeting their standards are guaranteed to have the published strength and material properties for a designation.

A36 – carbon steel used for plates, angles $F_y = 36 \text{ ksi}$, $F_u = 58 \text{ ksi}$, E = 29,000 ksi A572 – high strength low-alloy use for some beams A992 – for building framing used for most beams $F_y = 60 \text{ ksi}$, $F_u = 75 \text{ ksi}$, E = 30,000 ksi $F_y = 50 \text{ ksi}$, $F_u = 65 \text{ ksi}$, E = 30,000 ksi (A572 Grade 50 has the same properties as A992)

 $\underline{ASD} \qquad R_a \leq \frac{R_n}{\Omega}$

where R_a = required strength (dead or live; force, moment or stress)

 R_n = nominal strength specified for ASD

 Ω = safety factor

Factors of Safety are applied to the limit stresses for allowable stress values:

 $\begin{array}{ll} \mbox{bending (braced, $L_b < L_p$)} & \Omega = 1.67 \\ \mbox{bending (unbraced, $L_p < L_b$ and $L_b > L_r$)} & \Omega = 1.67 \mbox{ (nominal moment reduces)} \\ \mbox{shear (beams)} & \Omega = 1.5 \mbox{ or } 1.67 \\ \mbox{shear (bolts)} & \Omega = 2.00 \mbox{ (tabular nominal strength)} \\ \mbox{shear (welds)} & \Omega = 2.00 \end{array}$

- L_b is the unbraced length between bracing points, laterally
- L_p is the limiting laterally unbraced length for the limit state of yielding
- $L_{\rm r}$ is the limiting laterally unbraced length for the limit state of inelastic lateral-torsional buckling

LRFD $R_u \leq \phi R_n \qquad where \cdots R_u = \Sigma \gamma_i R_i$ where $\phi = \text{resistance factor}$ $\gamma = \text{load factor for the type of load}$ R = load (dead or live; force, moment or stress) $R_u = \text{factored load (moment or stress)}$ $R_n = \text{nominal load (ultimate capacity; force, moment or stress)}$

Nominal strength is defined as the

capacity of a structure or component to resist the effects of loads, as determined by computations using specified material strengths (such as yield strength, F_y , or ultimate strength, F_u) and dimensions and formulas derived from accepted principles of structural mechanics or by field tests or laboratory tests of scaled models, allowing for modeling effects and differences between laboratory and field conditions

Factored Load Combinations

The design strength, ϕR_n , of each structural element or structural assembly must equal or exceed the design strength based on the ASCE-7 (2010) combinations of factored nominal loads:

$$1.4D$$

$$1.2D + 1.6L + 0.5(L_r \text{ or } S \text{ or } R)$$

$$1.2D + 1.6(L_r \text{ or } S \text{ or } R) + (L \text{ or } 0.5W)$$

$$1.2D + 1.0W + L + 0.5(L_r \text{ or } S \text{ or } R)$$

$$1.2D + 1.0E + L + 0.2S$$

$$0.9D + 1.0W$$

$$0.9D + 1.0E$$

Criteria for Design of Beams

Allowable normal stress or normal stress from LRFD should not be exceeded:

$$F_b \text{ or } \phi F_n \ge f_b = \frac{Mc}{I}$$
$$(M_a \le M_n / \Omega \text{ or } M_u \le \phi_b M_n)$$

Knowing M and F_b , the minimum section modulus fitting the limit is:

$$S_{\mathit{req'd}} \geq \frac{M}{F_b}$$

Determining Maximum Bending Moment

Drawing V and M diagrams will show us the maximum values for design. Remember:

$$V = \Sigma(-w)dx$$

$$M = \Sigma(V)dx$$

$$\frac{dV}{dx} = -w$$

$$\frac{dM}{dx} = V$$

Determining Maximum Bending Stress

For a prismatic member (constant cross section), the maximum normal stress will occur at the maximum moment.

For a *non-prismatic* member, the stress varies with the cross section AND the moment.

Deflections

If the bending moment changes, M(x) across a beam of constant material and cross section then the curvature will change: $\frac{1}{R} = \frac{M(x)}{EI}$

The slope of the n.a. of a beam, θ , will be tangent to the radius of curvature, R: $\theta = slope = \frac{1}{EI} \int M(x) dx$

The equation for deflection, y, along a beam is: $y = \frac{1}{EI} \int \theta dx = \frac{1}{EI} \iint M(x) dx$

Elastic curve equations can be found in handbooks, textbooks, design manuals, etc...Computer programs can be used as well. Elastic curve equations can be superimposed ONLY if the stresses are in the elastic range.

The deflected shape is roughly the same shape flipped as the bending moment diagram but is constrained by supports and geometry.

Allowable Deflection Limits

All building codes and design codes limit deflection for beam types and damage that could happen based on service condition and severity.

$$y_{\text{max}}(x) = \Delta_{actual} \le \Delta_{allowable} = \frac{L}{value}$$

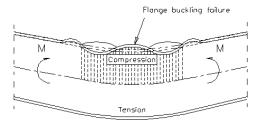

Use	LL only	DL+LL
Roof beams:		
Industrial	L/180	L/120
Commercial		
plaster ceiling	L/240	L/180
no plaster	L/360	L/240
Floor beams:		
Ordinary Usage	L/360	L/240
Roof or floor (damageable	e elements)	L/480

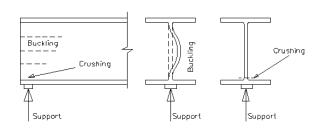

Lateral Buckling

With compression stresses in the top of a beam, a sudden "popping" or buckling can happen even at low stresses. In order to prevent it, we need to brace it along the top, or laterally brace it, or provide a bigger I_y .

Local Buckling in Steel I Beams- Web Crippling or Flange Buckling

Concentrated forces on a steel beam can cause the web to buckle (called **web crippling**). Web stiffeners under the beam loads and bearing plates at the supports reduce that tendency. Web stiffeners also prevent the web from shearing in plate girders.

The maximum support load and interior load can be determined from:

$$P_{n \text{ (max -end)}} = (2.5k + N)F_{yw}t_w$$

$$P_{n \text{ (interior)}} = (5k + N)F_{yw}t_w$$

where

 t_w = thickness of the web

 F_{yw} = yield strength of the web

N =bearing length

k = dimension to fillet found in beam section tables

$$\phi = 1.00 \, (LRFD)$$
 $\Omega = 1.50 \, (ASD)$

Beam Loads & Load Tracing

In order to determine the loads on a beam (or girder, joist, column, frame, foundation...) we can start at the top of a structure and determine the <u>tributary area</u> that a load acts over and the beam needs to support. Loads come from material weights, people, and the environment. This area is assumed to be from half the distance to the next beam over to halfway to the next beam.

The reactions must be supported by the next lower structural element *ad infinitum*, to the ground.

LRFD - Bending or Flexure

For determining the flexural design strength, $\phi_b M_n$, for resistance to pure bending (no axial load) in most flexural members where the following conditions exist, a single calculation will suffice:

$$\Sigma \gamma_i R_i = M_u \le \phi_b M_n = 0.9 F_y Z$$

where

 $M_u = maximum \ moment \ from \ factored \ loads$

 ϕ_b = resistance factor for bending = 0.9

 M_n = nominal moment (ultimate capacity)

 F_y = yield strength of the steel

 \vec{Z} = plastic section modulus

Plastic Section Modulus

Plastic behavior is characterized by a yield point and an increase in strain with no increase in stress.

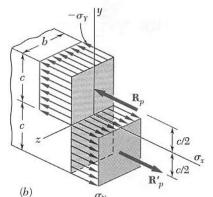

Internal Moments and Plastic Hinges

Plastic hinges can develop when all of the material in a cross section sees the yield stress. Because all the material at that section can strain without any additional load, the member segments on either side of the hinge can rotate, possibly causing instability.

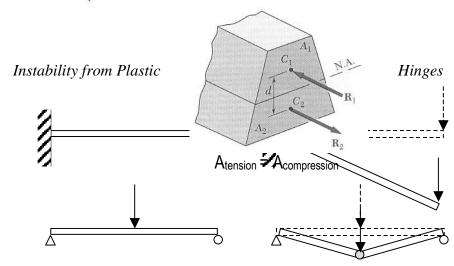

For a rectangular section:

Elastic to
$$f_y$$
: $M_y = \frac{I}{c} f_y = \frac{bh^2}{6} f_y = \frac{b(2c)^2}{6} f_y = \frac{2bc^2}{3} f_y$

Fully Plastic: M_{ult} or $M_p = bc^2 f_y = \frac{3}{2} M_y$

For a non-rectangular section and internal equilibrium at σ_y , the n.a. will not necessarily be at the centroid. The n.a. occurs where the $A_{tension} = A_{compression}$. The reactions occur at the centroids of the tension and compression areas.

Shape Factor:

The ratio of the plastic moment to the elastic moment at yield:

$$k = \frac{M_p}{M_y}$$
 k = 3/2 for a rectangle $k \approx 1.1$ for an I beam

Plastic Section Modulus

$$Z = \frac{M_p}{f_y} \quad and \quad k = \frac{Z}{S}$$

Design for Shear

$$V_a \leq V_n / \Omega$$
 or $V_u \leq \phi_v V_n$

The nominal shear strength is dependent on the cross section shape. Case 1: With a thick or stiff web, the shear stress is resisted by the web of a wide flange shape (with the exception of a handful of W's). Case 2: When the web is not stiff for doubly symmetric shapes, singly symmetric shapes (like channels) (excluding round high strength steel shapes), inelastic web buckling occurs. When the web is very slender, elastic web buckling occurs, reducing the capacity even more:

Case 1) For
$$h/t_w \le 2.24 \sqrt{\frac{E}{F_y}}$$
 $V_n = 0.6 F_{yw} A_w$ $\phi_v = 1.00 \text{ (LRFD)}$ $\Omega = 1.50 \text{ (ASD)}$

where *h* equals the clear distance between flanges less the fillet or corner radius for rolled shapes

 V_n = nominal shear strength F_{vw} = vield strength of the steel

 $F_{yw} = yield$ strength of the steel in the web

 $A_w = t_w d = area of the web$

Case 2) For
$$h/t_w > 2.24 \sqrt{\frac{E}{F_v}}$$
 $V_n = 0.6 F_{yw} A_w C_v$ $\phi_v = 0.9$ (LRFD) $\Omega = 1.67$ (ASD)

where C_v is a reduction factor (1.0 or less by equation)

Design for Flexure

$$M_a \le M_n / \Omega$$
 or $M_u \le \phi_b M_n$ $\phi_b = 0.90 \text{ (LRFD)}$ $\Omega = 1.67 \text{ (ASD)}$

The nominal flexural strength M_n is the *lowest* value obtained according to the limit states of

- 1. yielding, limited at length $L_p = 1.76r_y \sqrt{\frac{E}{F_y}}$, where r_y is the radius of gyration in y
- 2. lateral-torsional buckling limited at length L_r
- 3. flange local buckling
- 4. web local buckling

Beam design charts show available moment, M_n/Ω and $\phi_b M_n$, for unbraced length, L_b , of the compression flange in one-foot increments from 1 to 50 ft. for values of the bending coefficient $C_b = 1$. For values of $1 < C_b \le 2.3$, the required flexural strength M_u can be reduced by dividing it by C_b . ($C_b = 1$ when the bending moment at any point within an unbraced length is larger than that at both ends of the length. C_b of 1 is conservative and permitted to be used in any case. When the free end is unbraced in a cantilever or overhang, $C_b = 1$. The full formula is provided below.)

NOTE: the self weight is not included in determination of M_n/Ω $\phi_h M_n$

Compact Sections

For a laterally braced *compact* section (one for which the plastic moment can be reached before local buckling) only the limit state of yielding is applicable. For unbraced compact beams and non-compact tees and double angles, only the limit states of yielding and lateral-torsional buckling are applicable.

Compact sections meet the following criteria: $\frac{b_f}{2t_f} \le 0.38 \sqrt{\frac{E}{F_y}}$ and $\frac{h_c}{t_w} \le 3.76 \sqrt{\frac{E}{F_y}}$

where:

 b_f = flange width in inches

 t_f = flange thickness in inches

E =modulus of elasticity in ksi

 F_{ν} = minimum yield stress in ksi

 h_c = height of the web in inches

 t_w = web thickness in inches

With lateral-torsional buckling the nominal flexural strength is

$$M_n = C_b \left[M_p - (M_p - 0.7F_y S_x) \left(\frac{L_b - L_p}{L_r - L_p} \right) \right] \le M_p$$

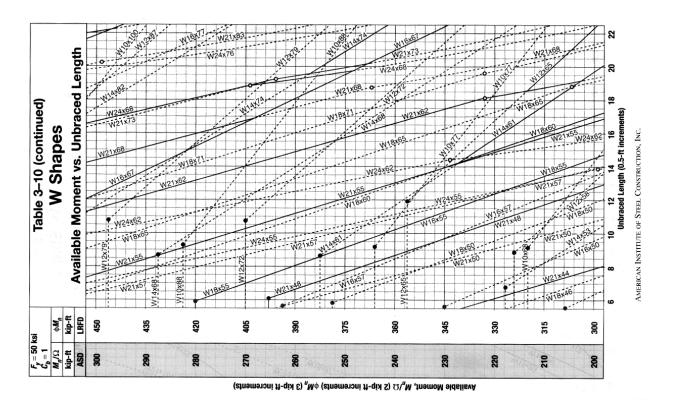

where C_b is a modification factor for non-uniform moment diagrams where, when both ends of the beam segment are braced:

$$C_b = \frac{12.5M_{max}}{2.5M_{max} + 3M_A + 4M_B + 3M_C}$$

 M_{max} = absolute value of the maximum moment in the unbraced beam segment M_A = absolute value of the moment at the quarter point of the unbraced beam segment M_B = absolute value of the moment at the center point of the unbraced beam segment M_C = absolute value of the moment at the three quarter point of the unbraced beam segment length.

Available Flexural Strength Plots

Plots of the available moment for the unbraced length for wide flange sections are useful to find sections to satisfy the design criteria of $M_a \leq M_n / \Omega$ or $M_u \leq \phi_b M_n$. The maximum moment that can be applied on a beam (taking self weight into account), M_a or M_u , can be plotted against the unbraced length, L_b . The limiting length, L_p (fully plastic), is indicated by a solid dot (\bullet), while the limiting length, L_r (for lateral torsional buckling), is indicated by an open dot (\bigcirc). Solid lines indicate the most economical, while dashed lines indicate there is a lighter section that could be used. C_b , which is a modification factor for non-zero moments at the ends, is 1 for simply supported beams (0 moments at the ends). (see *figure*)

Design Procedure

The intent is to find the most light weight member (which is economical) satisfying the section modulus size.

- 1. Determine the unbraced length to choose the limit state (yielding, lateral torsional buckling or more extreme) and the factor of safety and limiting moments. Determine the material.
- 2. Draw V & M, finding V_{max} and M_{max} .for unfactored loads (ASD, $V_a \& M_a$) or from factored loads (LRFD, $V_u \& M_u$)
- 3. Calculate $Z_{\text{req'd}}$ when yielding is the limit state. This step is equivalent to determining if $f_b = \frac{M_{max}}{S} \le F_b$, $Z_{req'd} \ge \frac{M_{max}}{F_b} = \frac{M_{max}}{F_y}$ and $Z_{req'd} \ge \frac{M_u}{\phi_b F_y}$ to meet the design criteria that

$$M_a \le M_n / \Omega$$
 or $M_u \le \phi_b M_n$

If the limit state is something other than yielding, determine the nominal moment, M_n , or use plots of available moment to unbraced length, L_b .

4. For steel: use the section charts to find a trial Z and remember that the beam self weight (the second number in the section designation) will increase $Z_{req'd}$. The design charts show the lightest section within a grouping of similar Z's.

TABLE 9.1 Load Factor Resistance Design Selection

^{****} Determine the "updated" V_{max} and M_{max} including the beam self weight, and verify that the updated $Z_{req'd}$ has been met.*****

- 5. Consider lateral stability.
- 6. Evaluate horizontal shear using V_{max} . This step is equivalent to determining if $f_v \leq F_v$ is satisfied to meet the design criteria that $V_a \leq V_n / \Omega$ or $V_u \leq \phi_v V_n$

For I beams:
$$f_{v-\text{max}} = \frac{3V}{2A} \approx \frac{V}{A_{web}} = \frac{V}{t_w d}$$

$$V_n = 0.6F_{yw}A_w \quad or \ V_n = 0.6F_{yw}A_w C_v$$
 Others:
$$f_{v-\text{max}} = \frac{VQ}{Ib}$$

- 7. Provide adequate bearing area at supports. This step is equivalent to determining if $f_p = \frac{P}{A} \le F_p$ is satisfied to meet the design criteria that $P_a \le P_n / \Omega$ or $P_u \le \phi P_n$
- 8. Evaluate shear due to torsion $f_{v} = \frac{T\rho}{J} \text{ or } \frac{T}{c_{1}ab^{2}} \le F_{v} \text{ (circular section or rectangular)}$
- 9. Evaluate the deflection to determine if $\Delta_{maxLL} \leq \Delta_{LL-allowed}$ and/or $\Delta_{maxTotal} \leq \Delta_{Total allowed}$
- **** note: when $\Delta_{calculated} > \Delta_{limit}$, $I_{req'd}$ can be found with: and $Z_{req'd}$ will be satisfied for similar self weight ***** $I_{req'd} \geq \frac{\Delta_{loobig}}{\Delta_{limit}} I_{trial}$

FOR ANY EVALUATION:

Redesign (with a new section) at any point that a stress or serviceability criteria is NOT satisfied and re-evaluate each condition until it is satisfactory.

Load Tables for Uniformly Loaded Joists & Beams

Tables exist for the common loading situation of uniformly distributed load. The tables either provide the safe distributed load based on bending and deflection limits, they give the allowable span for specific live and dead loads including live load deflection limits.

If the load is *not uniform*, an *equivalent uniform load* can be calculated $M_{max} = \frac{w_{equivalent}L^2}{8}$ from the maximum moment equation:

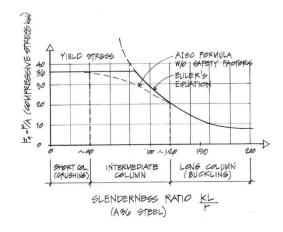

If the deflection limit is less, the design live load to check against allowable must be increased, ex.

$$w_{adjusted} = w_{ll-have} \left(\frac{L/360}{L/400} \right)$$
 table limit wanted

Criteria for Design of Columns

If we know the loads, we can select a section that is adequate for strength & buckling.

If we know the length, we can find the limiting load satisfying strength & buckling.

Allowable Stress Design

American Institute of Steel Construction (AISC) Manual of ASD, 9th ed:

<u>Long and slender:</u> [$L_e/r \ge C_c$, preferably < 200]

$$F_{allowable} = \frac{F_{cr}}{F.S.} = \frac{12\pi^2 E}{23(Kl/r)^2}$$

The yield limit is idealized into a parabolic curve that blends into the Euler's Formula at C_c.

With $F_y = 36$ ksi, $C_c = 126.1$

With $F_y = 50$ ksi, $C_c = 107.0$

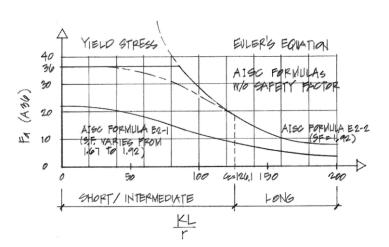

$$C_c = \sqrt{\frac{2\pi^2 E}{F_y}}$$

Short and stubby: $[L_e/r < C_c]$

$$F_a = \left[1 - \frac{\left(\frac{Kl}{r}\right)^2}{2C_c^2}\right] \frac{F_y}{F.S.}$$

with:

$$F.S. = \frac{5}{3} + \frac{3(Kl/r)}{8C_c} - \frac{(Kl/r)^3}{8C_c^3}$$

Design for Compression

American Institute of Steel Construction (AISC) Manual 14th ed:

 $P_a \le P_n / \Omega$ or $P_u \le \phi_c P_n$ where $P_u = \sum \gamma_i P_i$

 γ is a <u>load factor</u>

P is a load type

 $\boldsymbol{\varphi}$ is a <u>resistance factor</u>

P_n is the <u>nominal load capacity (strength)</u>

$$\phi = 0.90 \; (LRFD) \qquad \Omega = 1.67 \; (ASD)$$

For compression $P_n = F_{cr} A_g$

where: A_g is the cross section area and F_{cr} is the flexural buckling stress

The flexural buckling stress, F_{cr} , is determined as follows:

when
$$\frac{KL}{r} \le 4.71 \sqrt{\frac{E}{F_y}}$$
 or $(F_e \ge 0.44F_y)$:
$$F_{cr} = \left[0.658^{\frac{F_y}{F_e}}\right] F_y$$
when $\frac{KL}{r} > 4.71 \sqrt{\frac{E}{F_y}}$ or $(F_e < 0.44F_y)$:
$$F_{cr} = 0.877 F_e$$

where F_e is the elastic critical buckling stress:

$$F_e = \frac{\pi^2 E}{\left(\frac{KL}{r}\right)^2}$$

Design Aids

Tables exist for the value of the flexural buckling stress based on slenderness ratio. In addition, tables are provided in the AISC Manual for Available Strength in Axial Compression based on the effective length with respect to least radius of gyration, r_y . If the critical effective length is about the largest radius of gyration, r_x , it can be turned into an effective length about the y axis with the fraction r_x/r_y .

Procedure for Analysis

- 1. Calculate KL/r for each axis (if necessary). The largest will govern the buckling load.
- 2. Find F_a or F_{cr} as a function of KL/r from the appropriate equation (above) or table.
- 3. Compute $P_{allowable} = F_a \cdot A$ or $P_n = F_{cr} \cdot A_g$ or alternatively compute $f_c = P/A$ or P_u/A
- 4. Is the design satisfactory?

Is
$$P \le P_{\text{allowable}}$$
 (or $P_a \le P_n/\Omega$) or $P_u \le \phi_c P_n$? \Rightarrow yes, it is; no, it is no good or Is $f_c \le F_a$ (or $\le F_{cr}/\Omega$) or $\phi_c F_{cr}$? \Rightarrow yes, it is; no, it is no good

Procedure for Design

- 1. Guess a size by picking a section.
- 2. Calculate KL/r for each axis (if necessary). The largest will govern the buckling load.
- 3. Find F_a or F_{cr} as a function of KL/r from appropriate equation (above) or table.
- 4. Compute $P_{allowable} = F_a \cdot A$ or $P_n = F_{cr} \cdot A_g$ or alternatively compute $f_c = P/A$ or P_u/A
- 5. Is the design satisfactory?
 - Is $P \le P_{\text{allowable}} (P_a \le P_n/\Omega)$ or $P_u \le \phi_c P_n$? yes, it is; no, pick a bigger section and go back to step 2.
 - Is $f_c \le F_a$ ($\le F_{cr}/\Omega$) or $\phi_c F_{cr}$? \Rightarrow yes, it is; no, pick a bigger section and go back to step 2.
- 6. Check design efficiency by calculating percentage of stress used:=

$$\frac{P}{P_{allowable}} \cdot 100\% \left(\frac{P_a}{P_n/\Omega} \cdot 100\% \right) or \frac{P_u}{\phi_c P_n} \cdot 100\%$$

If value is between 90-100%, it is efficient.

If values is less than 90%, pick a smaller section and go back to step 2.

Columns with Bending (Beam-Columns)

In order to *design* an adequate section for allowable stress, we have to start somewhere:

- 1. Make assumptions about the limiting stress from:
 - buckling
 - axial stress
 - combined stress
- 2. See if we can find values for \underline{r} or \underline{A} or \underline{Z}
- 3. Pick a trial section based on if we think r or A is going to govern the section size.

- 4. Analyze the stresses and compare to allowable using the allowable stress method or interaction formula for eccentric columns.
- 5. Did the section pass the stress test?
 - If not, do you *increase* r or A or Z?
 - If so, is the difference really big so that you could *decrease* r or A or Z to make it more efficient (economical)?
- 6. Change the section choice and go back to step 4. Repeat until the section meets the stress criteria.

Design for Combined Compression and Flexure:

The interaction of compression and bending are included in the form for two conditions based on the size of the required axial force to the available axial strength. This is notated as P_r (either P from ASD or P_u from LRFD) for the axial force being supported, and P_c (either P_n/Ω for ASD or $\phi_c P_n$ for LRFD). The increased bending moment due to the P- Δ effect must be determined and used as the moment to resist.

For
$$\frac{P_{r}}{P_{c}} \ge 0.2$$
: $\frac{P}{P_{n}/\Omega} + \frac{8}{9} \left(\frac{M_{x}}{M_{nx}/\Omega} + \frac{M_{y}}{M_{ny}/\Omega} \right) \le 1.0$ $\frac{P_{u}}{\phi_{c}P_{n}} + \frac{8}{9} \left(\frac{M_{ux}}{\phi_{b}M_{nx}} + \frac{M_{uy}}{\phi_{b}M_{ny}} \right) \le 1.0$ (ASD) (LRFD)

For $\frac{P_{r}}{P_{c}} < 0.2$: $\frac{P}{2P_{n}/\Omega} + \left(\frac{M_{x}}{M_{nx}/\Omega} + \frac{M_{y}}{M_{ny}/\Omega} \right) \le 1.0$ $\frac{P_{u}}{2\phi_{c}P_{n}} + \left(\frac{M_{ux}}{\phi_{b}M_{nx}} + \frac{M_{uy}}{\phi_{b}M_{ny}} \right) \le 1.0$

where:

$$\begin{array}{ll} \text{for compression} & \phi_c = 0.90 \; (LRFD) & \Omega = 1.67 \; (ASD) \\ \text{for bending} & \phi_b = 0.90 \; (LRFD) & \Omega = 1.67 \; (ASD) \end{array}$$

For a <u>braced</u> condition, the moment magnification factor B_I is determined by $B_1 = \frac{C_m}{1 - (P_u/P_{el})} \ge 1.0$

(LRFD)

where C_m is a modification factor accounting for end conditions

When not subject to transverse loading between supports in plane of bending:

= 0.6 - 0.4 (M₁/M₂) where M₁ and M₂ are the end moments and M₁<M₂. M₁/M₂ is positive when the member is bent in reverse curvature (same direction), negative when bent in single curvature.

When there is transverse loading between the two ends of a member:

= 0.85, members with restrained (fixed) ends

= 1.00, members with unrestrained ends

$$P_{e1} = \frac{\pi^2 EA}{\left(\frac{Kl}{r}\right)^2}$$

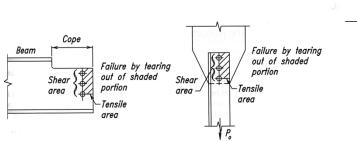

P_{e1} =Euler buckling strength

(ASD)

Criteria for Design of Connections

Connections must be able to transfer any axial force, shear, or moment from member to member or from beam to column.

Connections for steel are typically high strength bolts and electric arc welds. Recommended practice for ease of construction is to specified *shop welding* and *field bolting*.

Small tension force

Large tension force

Large tension force

P_o

Small shear force

(a)

(b)

Fig. C-J4.1. Failure for block shear rupture limit state.

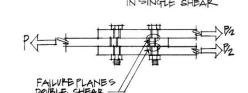

Fig. C-J4.2. Block shear rupture in tension.

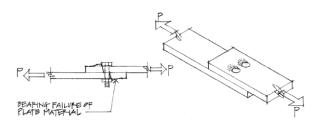

Bolted and Welded Connections

The limit state for connections depends on the loads:

- 1. tension yielding
- 2. shear yielding
- 3. bearing yielding
- 4. bending yielding due to eccentric loads
- 5. rupture

Welds must resist shear stress. The design strengths depend on the weld materials.

Bolted Connection Design

Bolt designations signify material and type of connection where

SC: slip critical

N: bearing-type connection with bolt threads *included* in shear plane

X: bearing-type connection with bolt threads excluded from shear plane

A307: similar in strength to A36 steel (also known as ordinary, common or unfinished bolts)

A325: high strength bolts

A490: high strength bolts (higher than A325)

Bearing-type connection: no frictional resistance in the contact surfaces is assumed and slip between members occurs as the load is applied. (Load transfer through bolt only).

Slip-critical connections: bolts are torqued to a high tensile stress in the shank, resulting in a clamping force on the connected parts. (Shear resisted by clamping force). Requires inspections and is useful for structures seeing dynamic or fatigue loading.

Bolts rarely fail in **bearing**. The material with the hole will more likely yield first.

For the determination of the net area of a bolt hole the width is taken as 1/16" greater than the nominal dimension of the hole. Standard diameters for bolt holes are 1/16" larger than the bolt diameter. (This means the net width will be 1/8" larger than the bolt.)

Design for Bolts in Bearing, Shear and Tension

Available shear values are given by bolt type, diameter, and loading (Single or Double shear) in AISC manual tables. Available shear value for slip-critical connections are given for limit states of serviceability or strength by bolt type, hole type (standard, short-slotted, long-slotted or oversized), diameter, and loading. Available tension values are given by bolt type and diameter in AISC manual tables.

Available bearing force values are given by bolt diameter, ultimate tensile strength, F_u , of the connected part, and thickness of the connected part in AISC manual tables.

For shear OR tension (same equation) in bolts:

$$R_a \le R_n / \Omega \text{ or } R_u \le \phi R_n$$

where $R_u = \sum \gamma_i R_i$

• single shear (or tension) $R_n = F_n A_b$

• double shear
$$R_n = F_n 2A_b$$

where $\phi =$ the resistance factor

 $F_n = \ the \ nominal \ tension \ or \ shear \ strength \ of \ the \ bolt$

 A_b = the cross section area of the bolt

$$\phi = 0.75 \text{ (LRFD)} \qquad \Omega = 2.00 \text{ (ASD)}$$

For bearing of plate material at bolt holes:

$$R_a \le R_n / \Omega \text{ or } R_u \le \phi R_n$$

where $R_u = \sum \gamma_i R_i$

• deformation at bolt hole is a concern

$$R_n = 1.2L_c t F_u \le 2.4 dt F_u$$

• deformation at bolt hole is not a concern

$$R_n = 1.5L_c t F_u \le 3.0 dt F_u$$

• long slotted holes with the slot perpendicular to the load

$$R_n = 1.0 L_c t F_u \le 2.0 dt F_u$$

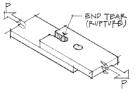

Figure 10.11 End tear-out.

where R_n = the nominal bearing strength

 F_u = specified minimum tensile strength

 L_c = clear distance between the edges of the hole and the next hole or edge in

the direction of the load nominal bolt diameter

t = thickness of connected material

 $\phi = 0.75 \text{ (LRFD)} \qquad \Omega = 2.00 \text{ (ASD)}$

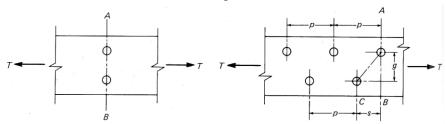

The *minimum* edge desistance from the center of the outer most bolt to the edge of a member is generally 134 times the bolt diameter for the sheared edge and 114 times the bolt diameter for the rolled or gas cut edges.

The maximum edge distance should not exceed 12 times the thickness of thinner member or 6 in.

Standard bolt hole spacing is 3 in. with the minimum spacing of $2\frac{2}{3}$ times the diameter of the bolt, d_b . Common edge distance from the center of last hole to the edge is $1\frac{1}{4}$ in..

Tension Member Design

In steel tension members, there may be bolt holes that reduce the size of the cross section.

g refers to the row spacing or gage

p refers to the bolt spacing or pitch

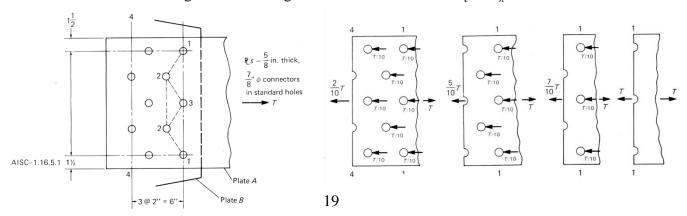

s refers to the longitudinal spacing of two consecutive holes

Effective Net Area:

The smallest effective are must be determined by subtracting the bolt hole areas. With staggered holes, the shortest length must be evaluated.

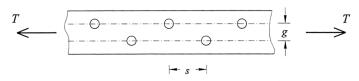

A series of bolts can also transfer a portion of the tensile force, and some of the effective net areas see reduced stress.

The effective net area, A_e , is determined from the net area, A_n multiplied by a shear lag factor, U, which depends on the element type and connection configuration. If a portion of a connected member is not fully connected (like the leg of an angle), the unconnected part is not subject to the full stress and the shear lag factor can range from 0.6 to 1.0: $A_e = A_n U$

The staggered hole path area is determined by:

$$A_n = A_g - A_{of \ all \ holes} + t\Sigma \frac{s^2}{4g}$$

where t is the plate thickness, s is each stagger spacing, and g is the gage spacing.

For tension elements:

$$R_a \le R_n / \Omega$$
 or $R_u \le \phi R_n$
where $R_u = \sum \gamma_i R_i$

1. yielding
$$R_n = F_y A_g$$

$$\phi = 0.90 \, (\text{LRFD}) \qquad \Omega = 1.67 \, (\text{ASD})$$

2. rupture
$$R_n = F_u A_e$$

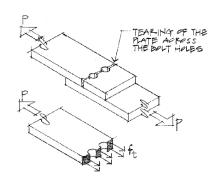

$$\phi = 0.75 \text{ (LRFD)} \qquad \Omega = 2.00 \text{ (ASD)}$$

 $\begin{array}{ll} \text{where} & A_g = \text{the gross area of the member} \\ & (\text{excluding holes}) \end{array}$

 A_e = the effective net area (with holes, etc.)

 F_y = the yield strength of the steel

 F_u = the tensile strength of the steel (ultimate)

Welded Connections

Weld designations include the strength in the name, i.e. E70XX has Fy = 70 ksi. Welds are weakest in shear and are assumed to always fail in the shear mode.

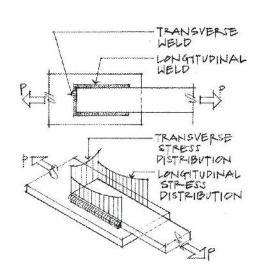

The throat size, T, of a fillet weld is determined trigonometry by: $T = 0.707 \times \text{weld size}^*$ * When the submerged arc weld process is used, welds over 3/8"

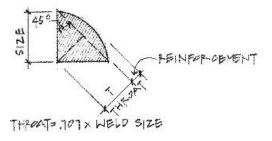

* When the submerged arc weld process is used, welds over 3/8" will have a throat thickness of 0.11 in. larger than the formula.

Weld sizes are limited by the size of the parts being put together and are given in AISC manual table J2.4 along with the allowable strength per length of fillet weld, referred to as *S*.

The maximum size of a fillet weld:

- a) can't be greater than the material thickness if it is ¼" or less
- b) is permitted to be 1/16" less than the thickness of the material if it is over 1/4"

The *minimum length* of a fillet weld is 4 times the nominal size. If it is not, then the weld size used for design is 1/4 the length.

Intermittent fillet welds cannot be less than four times the weld size, not to be less than 1 ½".

TABLE J2.4 Minimum Size of Fillet Welds

Material Thickness of Thicker	Minimum Size of Fillet
Part Joined (in.)	Weld ^a (in.)
To ¼ inclusive	1/e
Over ¼ to ½	3/16
Over ½ to ¾	1/4
Over ¾	5/16

AMERICAN INSTITUTE OF STEEL CONSTRUCTION

For fillet welds:

$$R_a \le R_n / \Omega$$
 or $R_u \le \phi R_n$
where $R_u = \sum \gamma_i R_i$

for the weld metal:
$$R_n = 0.6F_{EXX}Tl = Sl$$

$$\phi = 0.75 \text{ (LRFD)}$$
 $\Omega = 2.00 \text{ (ASD)}$

where:

T is throat thickness *l* is length of the weld

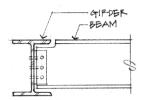

For a connected part, the other limit states for the base metal, such as tension yield, tension rupture, shear yield, or shear rupture **must** be considered.

Available	Strength of Fil	llet Welds
per	r inch of weld (φS)
Weld Size	E60XX	E70XX
(in.)	(k/in.)	(k/in.)
$\frac{3}{16}$	3.58	4.18
1/4	4.77	5.57
5/16	5.97	6.96
3/8	7.16	8.35
7/16	8.35	9.74
1/2	9.55	11.14
5/8	11.93	13.92
3/4	14.32	16.70

(not considering increase in throat with submerged arc weld process)

Framed Beam Connections

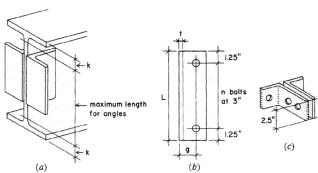

Coping is the term for cutting away part of the flange to connect a beam to another beam using welded or bolted angles.

AISC provides tables that give bolt and angle available strength knowing number of bolts, bolt type, bolt diameter, angle leg thickness, hole type and coping, and the wide flange beam being connected. For the connections the limit-state of bolt shear, bolts bearing on the angles, shear yielding of the angles, shear rupture of the angles, and block shear rupture of the angles, and bolt bearing on the beam web are considered.

Group A bolts include A325, while Group B includes A490.

There are also tables for bolted/welded double-angle connections and all-welded double-angle connections.

Limiting Strength or Stability States

In addition to resisting shear and tension in bolts and shear in welds, the connected materials may be subjected to shear, bearing, tension, flexure and even prying action. Coping can significantly reduce design strengths and may require web reinforcement. All the following must be considered:

- shear yielding
- shear rupture
- block shear rupture failure of a block at a beam as a
 result of shear and tension
- tension yielding
- tension rupture
- local web buckling
- lateral torsional buckling

Block Shear Strength (or Rupture):

$$R_a \le R_n / \Omega$$
 or $R_u \le \phi R_n$
where $R_u = \sum \gamma_i R_i$

$$\begin{split} R_n &= 0.6 F_u A_{nv} + U_{bs} F_u A_{nt} \leq 0.6 F_y A_{gv} + U_{bs} F_u A_{nt} \\ \phi &= 0.75 \text{ (LRFD)} \qquad \Omega = 2.00 \text{ (ASD)} \end{split}$$

where:

 A_{nv} is the net area subjected to shear

 A_{nt} is the net area subjected to tension

 A_{gv} is the gross area subjected to shear

 $U_{bs} = 1.0$ when the tensile stress is uniform (most cases)

= 0.5 when the tensile stress is non-uniform

Gusset Plates

Gusset plates are used for truss member connections where the geometry prevents the members from coming together at the joint "point". Members being joined are typically double angles.

Decking

Shaped, thin sheet-steel panels that span several joists or evenly spaced support behave as continuous beams. Design tables consider a "1 unit" wide strip across the supports and determine maximum bending moment and deflections in order to provide allowable loads depending on the depth of the material.

The other structural use of decking is to construct what is called a *diaphragm*, which is a horizontal unit tying the decking to the joists that resists forces parallel to the surface of the diaphragm.

When decking supports a concrete topping or floor, the steel-concrete construction is called *composite*.

Frame Columns

Because joints can rotate in frames, the effective length of the column in a frame is harder to determine. The stiffness (EI/L) of each member in a joint determines how rigid or flexible it is. To find k, the relative stiffness, G or Ψ , must be found for both ends, plotted on the alignment charts, and connected by a line for braced and unbraced fames.

$$G = \Psi = \frac{\sum EI/l_c}{\sum EI/l_t}$$

where

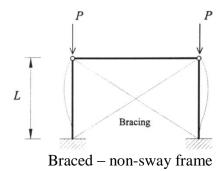

E = modulus of elasticity for a member

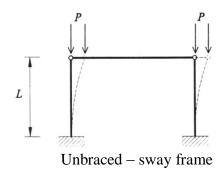

I = moment of inertia of for a member

 l_c = length of the column from center to center

 $l_{\rm b}$ = length of the beam from center to center

- For pinned connections we typically use a value of 10 for Ψ .
- For fixed connections we typically use a value of 1 for Ψ .

Nonsway Frames

Sway Frames

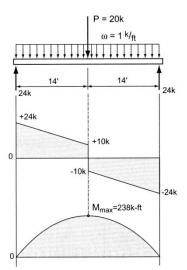

Example 1 (pg 330)

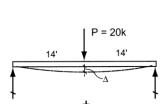

*Hypothetically determine the size of section required when the deflection criteria is NOT met

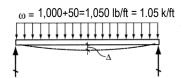

Example Problem 9.16 (Figures 9.76 to 9.78)

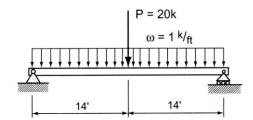

A steel beam (A572/50) is loaded as shown. Assuming a deflection requirement of $\Delta_{\rm total}$ = L/240 and a depth restriction of 18" nominal, select the most economical section. (unified ASD)

$$F_b = 30 \text{ ksi}$$
; $F_v = 20 \text{ ksi}$; $E = 30 \times 10^3 \text{ ksi}$ $F_v = 50 \text{ ksi}$

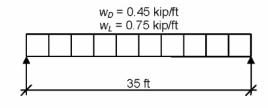

Given:

Select an ASTM A992 W-shape beam with a simple span of 35 feet. Limit the member to a maximum nominal depth of 18 in. Limit the live load deflection to L/360. The nominal loads are a uniform dead load of 0.45 kip/ft and a uniform live load of 0.75 kip/ft. Assume the beam is continuously braced. Use ASD of the Unified Design method.

Beam Loading & Bracing Diagram (full lateral support)

Solution:

Material Properties:

ASTM A992

 $F_v = 50 \text{ ksi}$

 $F_u = 65 \text{ ksi}$

- 1. The unbraced length is 0 because it says it is fully braced.
- 2. Find the maximum shear and moment from unfactored loads:

 $w_a = 0.450 \text{ k/ft} + 0.750 \text{ k/ft} = 1.20 \text{ k/ft}$

 $V_a = 1.20 \text{ k/ft}(35 \text{ ft})/2 = 21 \text{ k}$

 $M_a = 1.20 \text{ k/ft}(35 \text{ ft})^2/8 = 184 \text{ k-ft}$

If $M_a \le M_n/\Omega$, the maxmimum moment for design is $M_a\Omega$: $M_{max} = 184$ k-ft

3. Find Zreg'd:

 $Z_{\text{reg'd}} \ge M_{\text{max}}/F_b = M_{\text{max}}/\Omega)/F_v = 184 \text{ k-ft}(1.67)(12 \text{ in/ft})/50 \text{ ksi} = 73.75 \text{ in}^3 (F_v \text{ is the limit stress when fully braced})$

4. Choose a trial section, and also limit the depth to 18 in as instructed:

W18 x 40 has a plastic section modulus of 78.4 in³ and is the most light weight (as indicated by the bold text) in Table 9.1

Include the self weight in the maximum values:

 $w^*_{a-adjusted} = 1.20 \text{ k/ft} + 0.04 \text{ k/ft}$

 $V_{a-adjusted}^* = 1.24 \text{ k/ft}(35 \text{ ft})/2 = 21.7 \text{ k}$

 $M_{a-adjusted}^* = 1.24 \text{ k/ft}(35 \text{ ft})^3/8 = 189.9 \text{ k}$

 $Z_{\text{reg/d}} \ge 189.9 \text{ k-ft} (1.67) (12 \text{ in/ft})/50 \text{ ksi} = 76.11 \text{ in}^3$ And the Z we have (78.4) is larger than the Z we need (76.11), so OK.

Evaluate shear (is V_a ≤ V₀/Ω): A_w = dt_w so look up section properties for W18 x 40: d = 17.90 in and t_w = 0.315 in

 $V_n/\Omega = 0.6F_{yy}A_{yy}/\Omega = 0.6(50 \text{ ksi})(17.90 \text{ in})(0.315 \text{ in})/1.5 = 112.8 \text{ k which is much larger than } 21.7 \text{ k, so OK}$.

9. Evaluate the deflection with respect to the limit stated of L/360 for the live load. (If we knew the **total** load limit we would check that as well). The moment of inertia for the W18 x 40 is needed. I_x = 612 in⁴

 Δ live load limit = 35 ft(12 in/ft)/360 = 1.17 in

 Δ = 5wL⁴/384EI = 5(0.75 k/ft)(35 ft)⁴(12 in/ft)³/384(29 x 10³ ksi)(612 in⁴) = 1.42 in! This is TOO BIG (not less than the limit. Find the moment of inertia needed:

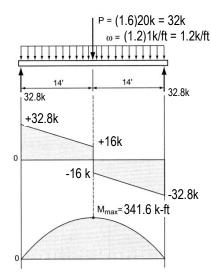

$$I_{req'd} \ge \Delta_{too\ big} (I_{trial})/\Delta_{limit} = 1.42\ in(612\ in^4)/(1.17\ in) = 742.8\ in^4$$

From Table 9.1, a W16 x 45 is larger (by Z), but not the most light weight (efficient), as is W10 x 68, W14 x 53, W18 x 46, (W21 x 44 is too deep) and W18 x 50 is bolded (efficient). (Now look up I's). (In order: $I_x = 586$, 394, 541, 712 and 800 in⁴)

Choose a W18 x 50

For the same beam and loading of Example 1, select the most economical beam using Load and Resistance Factor Design (LRFD) with the 18" depth restriction. Assume the distributed load is dead load, and the point load is live load. $F_v = 50$ ksi and $E = 30 \times 10^3$ ksi

- 1. To find $V_{u\text{-max}}$ and $M_{u\text{-max}}$, factor the loads, construct a *new* load diagram, shear diagram and bending moment diagram.
- 2. To satisfy $M_u \le \phi_b M_{n}$, we find $M_n = \frac{M_u}{\phi_b} = \frac{341.6^{k-ft}}{0.9} = 379.6^{k-ft}$ and solve for Z needed: $Z = \frac{M_n}{F_v} = \frac{379.6^{k-ft}(12^{in}/f_t)}{50ksi} = 91.1in^3$
 - Choose a *trial* section from the <u>Listing of W Shapes in Descending Order of Z</u> by selecting the **bold** section at the top of the grouping satisfying our Z and depth requirement W18 x 50 is the *lightest* with Z = 101 in³. (W22 x 44 is the lightest without the depth requirement.) Include the additional self weight (dead load) and find the maximum shear and bending moment:

$$\begin{split} &V_{u-adjusted}^* = 32.8k + \frac{1.2(50^{\,lb}/_{ft})28\,ft}{2(1000^{\,lb}/_{k})} = 33.64k \\ &M_{u-adjusted}^* = 341.6^{k-ft} + \frac{1.2(50^{\,lb}/_{ft})(28\,ft\,)^2}{8(1000^{\,lb}/_{k})} = 347.5^{k-ft} \\ &Z_{req'd}^* \geq \frac{M_u}{\phi_b F_v} = \frac{347.5^{k-ft}(12^{\,in}/_{ft})}{0.9(50ksi\,)} = 92.7in^3 \text{ , so Z (have) of 101 in}^3 \text{ is greater than the Z (needed)}. \end{split}$$

- 3. Check the shear capacity to satisfy $V_u \le \phi_v V_n$: $A_{web} = dt_w$ and d=17.99 in., $t_w = 0.355$ in. for the W18x50 $\phi_v V_n = \phi_v 0.6 F_{vw} A_w = 1.0(0.6)50 ksi(17.99in)0.355in = 191.6k$ So 33.64k \le 191.6 k OK
- 4. Calculate the deflection from the *unfactored* loads, including the self-weight now because it is known, and satisfy the deflection criteria of $\Delta_{LL} \leq \Delta_{LL-limit}$ and $\Delta_{total-limit}$. (This is <u>identical</u> to what is done in Example 1.) $I_x = 800 \text{ in}^3$ for the W18x50

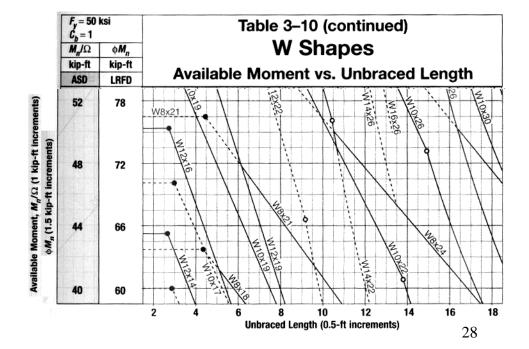

$$\Delta_{\text{total-limit}}$$
 = L/240 = 1.4 in., say Δ_{LL} = L/360 = 0.93 in

$$\Delta_{total} = \frac{PL^3}{48EI} + \frac{5wL^4}{384EI} = \frac{20k(28ft)^3(12^{in}/f_t)^3}{48(30x10^3ksi)800in^3} + \frac{5(1.050^{k/f_t})(28ft)^4(12^{in}/f_t)^3}{384(30x10^3ksi)800in^3} = 0.658 + 0.605 = 1.26in$$

So 1.26 in. \leq 1.4 in., and 0.658 in. \leq 0.93 in. OK

∴ FINAL SELECTION IS W18x50

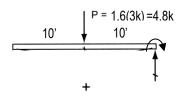

A steel beam with a 20 ft span is designed to be simply supported at the ends on columns and to carry a floor system made with open-web steel joists at 4 ft on center. The joists span 28 feet and frame into the beam from *one side only* and have a self weight of 8.5 lb/ft. Use A992 (grade 50) steel and select the most economical wide-flange section for the beam with LRFD design. Floor loads are 50 psf LL and 14.5 psf DL.

Select a A992 W shape flexural member ($F_y = 50$ ksi, $F_u = 65$ ksi) for a beam with distributed loads of 825 lb/ft (dead) and 1300 lb/ft (live) and a live point load at midspan of 3 k using the Available Moment tables. The beam is simply supported, 20 feet long, and braced at the ends and midpoint only ($L_b = 10$ ft.) The beam is a roof beam for an institution without plaster ceilings. (LRFD)

SOLUTION:

To use the Available Moment tables, the maximum moment required is plotted against the unbraced length. The first solid line with capacity or unbraced length *above* what is needed is the most economical.

w = 1.2(825 lb/ft) + 1.6(1300 lb/ft) = 3.07 k/ftDESIGN LOADS (load factors applied on figure):

$$M_{u} = \frac{wl^{2}}{2} + Pb = \frac{3.07 \frac{k}{f}(20 ft)^{2}}{2} + 4.8k(10 ft) = 662^{k-ft} \quad V_{u} = wl + P = 3.07 \frac{k}{f}(20 ft) + 4.8k = 66.2k$$

Plotting 662 k-ft vs. 10 ft lands just on the capacity of the W21x83, but it is dashed (and not the most economical) AND we need to consider the contribution of self weight to the total moment. Choose a *trial* section of W24 x 76. Include the new dead load:

$$M_{u-adjusted}^* = 662^{k-ft} + \frac{1.2(76^{lb}/f_t)(20ft)^2}{2(1000^{lb}/f_t)} 680.2^{k-ft} \qquad V_{u-adjusted}^* = 66.2k + 1.2(0.076 \frac{k}{f_t})(20ft) = 68.0k$$

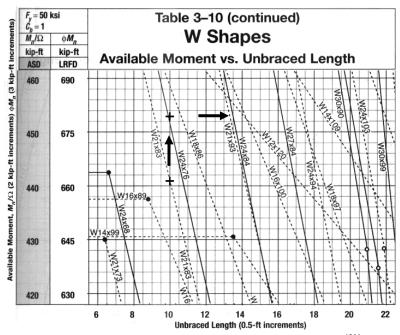

Replot 680.2 k-ft vs. 10ft, which lands *above* the capacity of the W21x83. We can't look up because the chart ends, but we can look for that capacity with a longer unbraced length. This leads us to a **W24** x **84** as the most economical. (With the additional self weight of 84 - 76 lb/ft = 8 lb/ft, the increase in the *factored* moment is only 1.92 k-ft; therefore, it is still OK.)

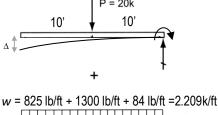

Evaluate the shear capacity:

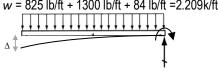

$$\phi_{v}V_{n} = \phi_{v}0.6F_{vw}A_{w} = 1.0(0.6)50ksi(24.10in)0.47in = 338.4k$$
 so yes, 68 k \leq 338.4k OK

Evaluate the deflection with respect to the limits of L/240 for live (unfactored) load and L/180 for total (unfactored) load: L/240 = 1 in. and L/180 = 1.33 in.

$$\Delta_{total} = \frac{Pb^2(3l-b)}{6EI} + \frac{wL^4}{24EI} = \frac{3k(10ft)^{12}(3\cdot20-10ft)(12\frac{i\eta_{ft}}{10})^3}{6(30x10^3ksi)2370in^3} + \frac{(2.209\frac{k_{ft}}{10})(20ft)^4(12\frac{i\eta_{ft}}{10})^3}{24(30x10^3ksi)2370in^3} = 0.06 + 0.36 = 0.42in$$

So, $\Delta_{LL} \leq \Delta_{LL-limit}$ and $\Delta_{total} \leq \Delta_{total-limit}$:

 $0.06 \text{ in.} \le 1 \text{ in.}$ and $0.42 \text{ in.} \le 1.33 \text{ in.}$

(This section is so big to accommodate the large bending moment at the cantilever support that it deflects very little.)

∴ FINAL SELECTION IS W24x84

Select the most economical joist for the 40 ft grid structure with floors and a flat roof. The roof loads are 10 lb/ft² dead load and 20 lb/ft² live load. The floor loads are 30 lb/ft² dead load 100 lb/ft² live load. (Live load deflection limit for the roof is L/240, while the floor is L/360). Use the (LRFD) K and LH series charts provided.

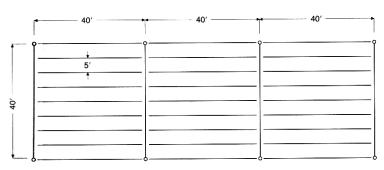

Figure 7.218 Framing plan for joists, girders, and columns on 40 ft \times 40 ft grid.

(Top values are maximum total factored load in lb/ft, while the lower (lighter) values are maximum (unfactored) live load for a deflection of L/360)

Shaded areas indicate the bridging requirements.

Example 7 (ASD)

EXAMPLE 5.1 Open-Web Steel Joist Design

A fully exposed roof system for a commercial building, spanning 35 ft, located in Muncie, Indiana, in an urban environment.

IBC specifies a **20 psf snow live load** for Muncie, Indiana, home of Ball State University. Table 1.3 indicates the snow exposure factor: $C_e = 0.9$. Table 1.4 indicates the snow thermal factor: $C_t = 1.0$. Table 1.7 indicates an occupancy importance factor (for Category II): $I_S = 1.0$. Fig. 1.2 indicates the ground snow load: $p_q = 20$ psf

$$P_S = 0.7(0.9)1.0(1.0)20 \text{ psf} = 13.9 \text{ psf}$$

A typical roof construction might consist of:

Membrane roofing1.0 psf4 in. average tapered rigid insulation6.0 psfSteel deck (2–4 ft span)1.0 psf

Estimated joist weight:

35 ft span would be a minimum 18 in. joist An average 18 in. joist weight = 9.0 plf

Spaced @ 4 ft-0 in. o.c. 9.0 plf/4 ft 2.3 psf Ceiling suspension system 1.0 psf 1_{2} in. gypsum ceiling 2.0 psf

Mechanical system estimates should also be included; the heavy sprinkler/drain piping running parallel to a joist or pair of joists is especially critical.

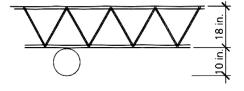

Miscellaneous ductwork/electrical 1.0 psf

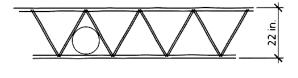

Total dead load 14.3 psf \times 4 ft o.c. = 57.2 plf Total live load 13.9 psf \times 4 ft o.c. = 55.6 plf Total live load + dead load = 112.8 plf

Use joist load tables to select the best section:

At 35 ft, 18K3 joists carry 149 plf TL and 77 plf LL LL: deflection controls and the weight is 6.6 plf.

At least on the surface, this is the best choice, but depending upon the need to integrate mechanical systems into the joist space, a 20K3 at 6.7 plf or even a 22K4 at 8.0 plf which is both deeper and heavier than the previous selection may be best:

STANDARD LOAD TABLE/OPEN WEB STEEL JOISTS, K-SERIES Based on a Maximum Allowable Tensile Stress of 30 ksi

A floor is to be supported by trusses spaced at 5 ft. on center and spanning 60 ft. having a dead load of 53 lb/ft² and a live load of 100 lb/ft². With 3 ft.-long panel points, the depth is assumed to be 3 ft with a span-to-depth ratio of 20. With 6 ft.-long panel points, the depth is assumed to be 6 ft with a span-to-depth ratio of 10. Determine the maximum force in a horizontal chord and the maximum force in a web member. Use factored loads. Assume a self weight of 40 lb/ft.

Table 7.2 Computation of Truss Joint Loads tributary widths Floor Factored Total Factored Node-Truss-Area Factored Load area loads Dead Live totoper 1.2 · P_{dead} + P_{dead} P_{live} Load Node Truss Node Load Wdead $1.6 \cdot P_{\text{live}}$ $1.6 \cdot P_{live}$ Spacing Spacing Α $(=w_{dead} \cdot A)$ $(=w_{live} \cdot A)$ $1.2 \cdot P_{\text{dead}}$ (K) (K/ft^2) (ft) (ft^2) (K) (K) (K) (#/ft2) (K/ft^2) (#/ft2) (ft) (K) Truss 3 ft 3.35 + 0.14 = 3.490.100 5 15 0.795 1.50 0.954 2.40 53 0.053 100 3 deep 6 ft 1.59 3.00 1.908 4.80 6.71 + 0.29 = 7.00100 0.100 30 53 0.053 deep 3 self weight 0.04 k/ft (distributed) $1.2P_{\text{dead}} = 1.2w_{\text{dead}} \cdot tributary \ width = 0.14 \ \text{K}$ $1.2P_{\text{dead}} = 1.2w_{\text{dead}} \cdot tributary \ width = 0.29 \ \text{K}$

FBD 3: Maximum web force will be in the end diagonal (just like maximum shear in a beam)

$$\Sigma F_y = 10P_1 - 0.5P_1 - F_{AB} \cdot \sin 45^\circ = 0$$

 $F_{AB} = 9.5P_1/\sin 45^\circ = 9.5(3.49 \text{ k})/0.707 = 46.9 \text{ k}$

FBD 1 for 3 ft deep truss

FBD 2 of cut just to the left of midspan

FBD 3 of cut just to right of left support

FBD 2: Maximum chord force (top or bottom) will be at midspan

$$\Sigma M_{G} = -9.5P_{1}(30^{ft}) + P_{1}(27^{ft}) + P_{1}(24^{ft}) + P_{1}(21^{ft}) + P_{1}(18^{ft})$$

$$+ P_{1}(15^{ft}) + P_{1}(12^{ft}) + P_{1}(9^{ft}) + P_{1}(6^{ft}) + P_{1}(3^{ft}) + T_{1}(3^{ft}) = 0$$

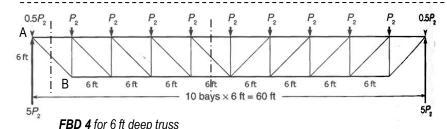

$$T_{1} = P_{1}(150^{ft})/3^{ft} = (3.49 \text{ k})(50) = 174.5 \text{ k}$$

$$\Sigma F_y = 10P_1 - 9.5P_1 - D_1 \cdot \sin 45^\circ = 0$$

 $D_1 = 0.5(3.49 \text{ k})/0.707 = 2.5 \text{ k}$ (minimum near midspan)

$$\Sigma F_x = -C_1 + T_1 + D_1 \cdot \cos 45^\circ = 0$$

 $C_1 = 176.2 k$

FBD 6: Maximum web force will be in the end diagonal

$$\Sigma F_y = 5P_2 - 0.5P_2 - F_{AB} \cdot \sin 45^\circ = 0$$

 $F_{AB} = 4.5P_2 \cdot \sin 45^\circ = 4.5(7 \text{ k}) \cdot 0.707 = 44.5 \text{ k}$

0.5P_o 0.5P C_2 6ft 6 ft 6 ft 5P, 5P,

FBD 5 of cut just to the left of midspan

 $\Sigma F_V = 5P_2 - 4.5P_1 - D_s \cdot \sin 45^\circ = 0$

 $D_2 = 0.5(7 \text{ k})/0.707 = 4.9 \text{ k}$ (minimum near midspan)

FBD 5: Maximum chord (top or bottom) force will be at midspan

 $T_2 = P_2(75^{ft})/6^{ft} = (7 \text{ k})(12.5) = 87.5 \text{ k}$

 $\Sigma M_G = -4.5P_2(30^{ft}) + P_2(24^{ft}) + P_2(18^{ft}) + P_2(12^{ft}) + P_2(6^{ft}) + T_2(6^{ft}) = 0$

FBD 6 of cut just to right $\Sigma F_x = -C_2 + T_2 + D_2 \cdot \cos 45^\circ = 0$ of left support

 $C_2 = 92.4 k$

Example 9 (pg 367) + LRFD Example Problem 10.10 (Figure 10.41)

A 24-ft.-tall, A572 grade 50, steel column (W14×82) with an F_y = 50 ksi has pins at both ends. Its weak axis is braced at midheight, but the column is free to buckle the full 24 ft. in the strong direction. Determine the safe load capacity for this column. using ASD and LRFD.

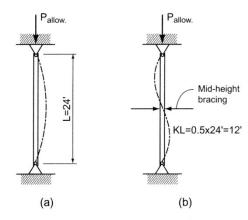

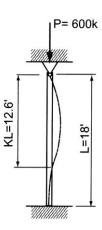

Figure 10.41 (a) Strong axis buckling. (b) Weak axis buckling.

Example 10 (pg 371) + chart method Example Problem 10.14: Design of Steel Columns (Figure 10.48)

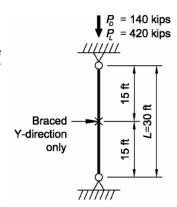

Select the most economical W12 \times column 18' in height to support an axial load of 600 kips using A572 grade 50 steel. Assume that the column is hinged at the top but fixed at the base. Use LRFD assuming that the load is a dead load (factor of 1.4)

ALSO: Select the W12 column using the Available Strength charts.

Given:

Redesign the column from Example E.1a assuming the column is laterally braced about the y-y axis and torsionally braced at the midpoint. Use both ASD and LRFD. $F_y = 50 \text{ ksi.}$ (Not using Available Strength charts)

Solution:

ASD:

- 1. $P_a = 140 k + 420 k = 560 k$
- 2. The effective length in the weak (y-y) axis is 15 ft, while the effective length in the strong (x-x) axis is 30 ft. (K = 1, KL = 1×30 ft). To find kL/ r_x and kL/ r_y we can assume or choose values from the wide flange charts. r_y 's range from 1 to 3 in., while r_x 's range from 3 to 14 inches. Let's try r_y = 2 in and r_x = 9 in. (something in the W21 range, say.)

$$kL/r_y \cong 15 \text{ ft}(12 \text{ in/ft})/2 \text{ in.} = 90 \iff GOVERNS \text{ (is larger)}$$

$$kL/r_x \cong 30 \text{ ft}(12 \text{ in/ft})/9 \text{ in.} = 40$$

3. Find a section with sufficient area (which then will give us "real" values for r_x and r_y):

If
$$P_a \le P_n/\Omega$$
, and $P_n = F_{cr} A$, we can find $A \ge P_a \Omega/F_{cr}$ with $\Omega = 1.67$

The tables provided have ϕF_{cr} , so we can get F_{cr} by dividing by $\phi = 0.9$

$$\phi F_{cr}$$
 for 90 is 24.9 ksi, $F_{cr} = 24.9 \text{ ksi}/0.9 = 27.67 \text{ ksi}$ so $A \ge 560 \text{ k}(1.67)/27.67 \text{ ksi} = 33.8 \text{ in}^2$

4. Choose a trial section, and find the effective lengths and associated available strength, F_{cr}:

Looking from the smallest sections, the W14's are the first with a big enough area:

Try a W14 x 120 (A = 35.3 in²) with
$$r_y$$
 = 3.74 in and r_x = 6.24 in.: kL/r_y = 48.1 and kL/r_x = 57.7 (GOVERNS)

 ϕF_{cr} for 58 is 35.2 ksi, $F_{cr} = 39.1$ ksi so A \geq 560 k(1.67)/39.1 ksi = 23.9 in²

Choose a W14 x 90 (Choosing a W14 x 82 would make kL/r_x = 59.5, and A_{req'd} = 24.3 in², which is more than 24.1 in²!)

LRFD:

- 1. $P_u = 1.2(140 \text{ k}) + 1.6(420 \text{ k}) = 840 \text{ k}$
- 2. The effective length in the weak (y-y) axis is 15 ft, while the effective length in the strong (x-x) axis is 30 ft. (K = 1, KL = 1×30 ft). To find kL/ r_x and kL/ r_y we can assume or choose values from the wide flange charts. r_y 's range from 1 to 3 in., while r_x 's range from 3 to 14 inches. Let's try r_y = 2 in and r_x = 9 in. (something in the W21 range, say.)

$$kL/r_y \cong 15 \text{ ft}(12 \text{ in/ft})/2 \text{ in.} = 90 \iff GOVERNS \text{ (is larger)}$$

$$kL/r_x \cong 30 \text{ ft}(12 \text{ in/ft})/9 \text{ in.} = 40$$

3. Find a section with sufficient area (which then will give us "real" values for rx and ry):

If
$$P_u \le \phi P_n$$
, and $\phi P_n = \phi F_{cr} A$, we can find $A \ge P_u/\phi F_{cr}$ with $\phi = 0.9$

$$\phi F_{cr}$$
 for 90 is 24.9 ksi, so A \geq 840 k/24.9 ksi = 33.7 in²

4. Choose a trial section, and find the effective lengths and associated available strength, φF_{cr}:

Looking from the smallest sections, the W14's are the first with a big enough area:

Try a W14 x 120 (A = 35.3 in²) with
$$r_v = 3.74$$
 in and $r_x = 6.24$ in.: $kL/r_v = 48.1$ and $kL/r_x = 57.7$ (GOVERNS)

 ϕF_{cr} for 58 is 35.2 ksi, so A \geq 840 k/35.2 ksi = 23.9 in²

Choose a W14 x 90 (Choosing a W14 x 82 would make kL/r_x = 59.5, and A_{req'd} = 24.3 in², which is more than 24.1 in²!)

Example 6-1:

For the building frame shown in Fig. 6-20, determine the effective column length factor, K, the slenderness ratio, KL/r for each column. Assume the columns buckle and the beams bend about their strong axis.

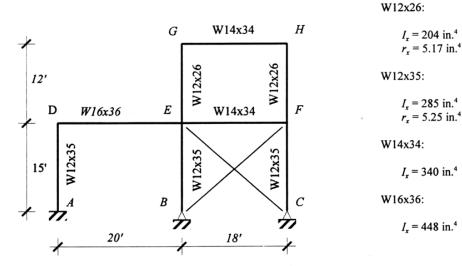

Figure 6-20: Building frame for Example 6-1.

Solution:

Note: The diagonal bracing prevents sidesway of the first story columns only.

$$G_{A} = 1.0 \text{ (fixed support)}$$

$$G_{B} = G_{C} = 10.0 \text{ (pinned support)}$$

$$G_{C} = \frac{\frac{285}{15}}{\frac{448}{20}} = 0.85$$

$$G_{C} = \frac{\frac{285}{15} + \frac{204}{12}}{\frac{448}{20} + \frac{340}{18}} = 0.87$$

$$G_{C} = \frac{\frac{285}{15} + \frac{204}{12}}{\frac{340}{18}} = 1.91$$

$$G_{C} = G_{C} = \frac{\frac{204}{12}}{\frac{340}{18}} = 0.90$$

Column	G_{Top}	G_{Bot}	K		KL/r
AD	0.85	1.0	0.76	Braced	0.76(15)(12)/5.25 = 26.1
BE	0.87	10.0	0.85	Braced	0.85(15)(12)/5.25 = 29.1
CF	1.91	10.0	0.90	Braced	0.90(15)(12)/5.25 = 30.9
EG	0.90	0.87	1.29	Unbraced	1.29(12)(12)/5.17 = 35.9
FH	0.90	1.91	1.43	Unbraced	1.43(12)(12)/5.17 = 39.8

Table 6-1: Column effective length factors and slenderness ratios for Example 6-1.

Investigate the accepatbility of a W16 x 67 used as a beam-column under the unfactored loading shown in the figure. It is A992 steel ($F_y = 50 \text{ ksi}$). Assume 25% of the load is dead load with 75% live load.

SOLUTION:

DESIGN LOADS (shown on figure):

Axial load = 1.2(0.25)(350k)+1.6(0.75)(350k)=525k

Moment at joint = $1.2(0.25)(60^{k-ft}) + 1.6(0.75)(60^{k-ft}) = 90^{k-ft}$

Determine column capacity and fraction to choose the appropriate interaction equation:

$$\begin{split} \frac{kL}{r_x} &= \frac{15 \, ft (12^{\frac{in}{f_f}})}{6.96 in} = 25.9 \quad \text{and} \quad \frac{kL}{r_y} = \frac{15 \, ft (12^{\frac{in}{f_f}})}{2.46 in} = 73 \quad \text{(governs)} \\ P_c &= \phi_c P_n = \phi_c F_{cr} A_g = (30.5 ksi) 19.7 in^2 = 600.85 k \\ \frac{P_r}{P_c} &= \frac{525 \, k}{600.85 \, k} = 0.87 > 0.2 \quad \text{so use} \quad \frac{P_u}{\phi_c P_n} + \frac{8}{9} \left(\frac{M_{ux}}{\phi_b M_{nx}} + \frac{M_{uy}}{\phi_b M_{ny}} \right) \leq 1.0 \end{split}$$

There is no bending about the y axis, so that term will not have any values.

Determine the bending moment capacity in the x direction:

The unbraced length to use the full plastic moment (L_p) is listed as 8.69 ft, and we are over that so of we don't want to determine it from formula, we can find the beam in the Available Moment vs. Unbraced Length tables. The value of ϕM_n at L_b =15 ft is 422 k-ft.

Determine the magnification factor when $M_1 = 0$, $M_2 = 90$ k-ft:

$$C_m = 0.6 - 0.4 \frac{M_1}{M_2} = 0.6 - \frac{0^{k-ft}}{90^{k-ft}} = 0.6 \le 1.0$$

$$P_{e1} = \frac{\pi^2 EA}{\left(\frac{Kl}{r}\right)^2} = \frac{\pi^2 (30x10^3 ksi)19.7 in^2}{\left(25.9\right)^2} = 8,695.4k$$

$$B_1 = \frac{C_m}{1 - \left(\frac{P_u}{P_{e1}}\right)} = \frac{0.6}{1 - \left(\frac{525k}{8695.4k}\right)} = 0.64 \ge 1.0$$
 USE 1.0 Mu = (1)90 k-ft

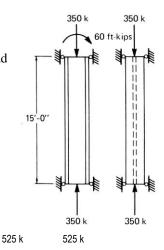

Finally, determine the interaction value:

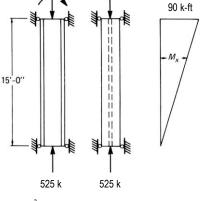

$$\frac{P_u}{\phi_c P_n} + \frac{8}{9} \left(\frac{M_{ux}}{\phi_b M_{nx}} + \frac{M_{uy}}{\phi_b M_{ny}} \right) = 0.87 + \frac{8}{9} \left(\frac{90^{k-ft}}{422^{k-ft}} \right) = 1.06 \le 1.0$$
 This is **NOT OK.** (and outside The section should be larger.

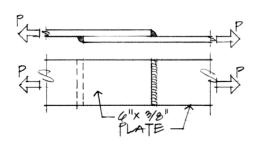

Example 14

10.9 Determine the maximum load carrying capacity of this lap joint., assuming A36 steel with E60XX electrodes.

10.7 Determine the capacity of the connection in Figure 10.44 assuming A36 steel with E70XX electrodes.

Solution:

Capacity of weld:

For a $\frac{5}{16}$ " fillet weld, $\phi S = 6.96$ k/in

Weld length = 8 in + 6 in + 8 in = 22 in.

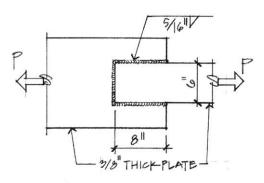

Weld capacity = $22'' \times 6.96$ k/in = 153.1 k

Capacity of plate:

$$\phi P_n = \phi F_y A_g \quad \phi = 0.9$$

Plate capacity = $0.9 \times 36 \text{ k/in}^2 \times 3/8'' \times 6'' = 72.9 \text{ k}$

∴ Plate capacity governs, $P_{\text{allow}} = 72.9 \text{ k}$

The weld size used is obviously too strong. What size, then, can the weld be reduced to so that the weld strength is more compatible to the plate capacity? To make the weld capacity \approx plate capacity:

 $22'' \times \text{(weld capacity per in.)} = 72.9 \text{ k}$

Weld capacity per inch = $\frac{72.9 \text{ k}}{22 \text{ in}}$ - 3.31 k/in.

From Available Strength table, use 3/16'' weld $(\phi S = 4.18 \text{ k/in.})$

Minimum size fillet = $\frac{3}{16}$ " based on a $\frac{3}{8}$ " thick plate.

Example 16

10.5 Using the AISC framed beam connection bolt shear in Table 7-1, determine the shear adequacy of the connection shown in Figure 10.28. What thickness and angle length are

required? Also determine the bearing capacity of the wide flange sections.

Factored end beam reaction = 90 k.

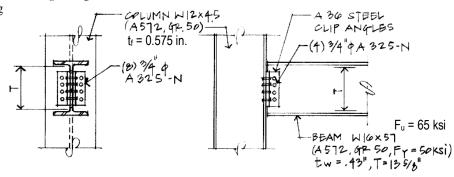

Figure 10.28 Typical beam-column connection.

10.2 The butt splice shown in Figure 10.22 uses two 8 x $\frac{3}{8}$ " plates to "sandwich" in the $8 \times \frac{1}{2}$ " plates being joined. Four \%"\phi A325-SC bolts are used on both sides of the splice. Assuming A36 steel and standard round holes, determine the allowable capacity of the connection.

0 CENTER PLATE

SOLUTION:

Shear, bearing and net tension will be checked to determine the critical conditions that governs the capacity of the connection.

Shear: Using the AISC available shear in Table 7-3 (Group A):

$$\phi R_n = 26.4 \text{ k/bolt x 4 bolts} = 105.6 \text{ k}$$

Bearing: Using the AISC available bearing in Table 7-4:

There are 4 bolts bearing on the center (1/2") plate, while there are 4 bolts bearing on a total width of two sandwich plates (3/4" total). The thinner bearing width will govern. Assume 3 in. spacing (center to center) of bolts. For A36 steel, $F_u = 58$ ksi.

$$\phi R_n = 91.4 \text{ k/bolt/in. x } 0.5 \text{ in. x } 4 \text{ bolts} = 182.8 \text{ k} \text{ (Table 7-4)}$$

With the edge distance of 2 in., the bearing capacity might be smaller from Table 7-5 which says the distance should be $2\frac{1}{4}$ in for full bearing (and we have 2 in.).

$$\phi R_0 = 89.6 \text{ k/bolt/in. x } 0.5 \text{ in. x } 4 \text{ bolts} = 179.2 \text{ k}$$

Tension: The center plate is critical, again, because its thickness is less than the combined thicknesses of the two outer plates. We must consider tension yielding and tension rupture:

$$\phi R_n = \phi F_v A_q$$
 and $\phi R_n = \phi F_u A_e$ where $A_e = A_{net} U$

$$A_g = 8 \text{ in. } x \frac{1}{2} \text{ in.} = 4 \text{ in}^2$$

The holes are considered 1/8 in. larger than the bolt hole diameter = (7/8 + 1/8) = 1.0 in.

$$A_n = (8 \text{ in.} - 2 \text{ holes } x \ 1.0 \text{ in.}) \ x \frac{1}{2} \text{ in.} = 3.0 \text{ in}^2$$

The whole cross section sees tension, so the shear lag factor U = 1

$$\phi F_{\nu} A_g = 0.9 \text{ x } 36 \text{ ksi x } 4 \text{ in}^2 = 129.6 \text{ k}$$

$$\phi F_u A_e = 0.75 \text{ x } 58 \text{ ksi x } (1) \text{ x } 3.0 \text{ in}^2 = 130.5 \text{ k}$$

Block Shear Rupture: It is possible for the center plate to rip away from the sandwich plates leaving the block (shown hatched) behind:

$$\phi R_n = \phi(0.6F_u A_{nv} + U_{bs} F_u A_{nt}) \le \phi(0.6F_v A_{qv} + U_{bs} F_u A_{nt})$$

where A_{nv} is the area resisting shear, A_{nt} is the area resisting tension, A_{gv} is the gross area resisting shear, and U_{bs} = 1 when the tensile stress is uniform.

$$A_{gv} = (4 + 2 \text{ in.}) \times \frac{1}{2} \text{ in.} = 3 \text{ in}^2$$

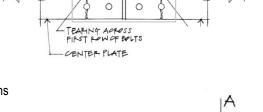

$$A_{nv} = A_{gv} - 1\frac{1}{2}$$
 holes area = $3 \text{ in}^2 - 1.5 \text{ x } 1 \text{ in. x } \frac{1}{2} \text{ in. = } 2.25 \text{ in}^2$

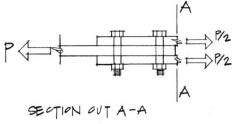

$$A_{nt} = 3.5 \text{ in. } x \text{ t} - 1 \text{ holes} = 3.5 \text{ in. } x \frac{1}{2} \text{ in} - 1 \text{ x} 1 \text{ in. } x \frac{1}{2} \text{ in.} = 1.25 \text{ in}^2$$

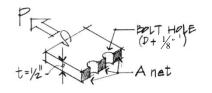

$$\phi(0.6F_uA_{nv} + U_{bs}F_uA_{nt}) = 0.75 \text{ x } (0.6 \text{ x } 58 \text{ ksi x } 2.25 \text{ in}^2 + 1 \text{ x } 58 \text{ ksi x } 1.25 \text{ in}^2) = 113.1 \text{ k}$$

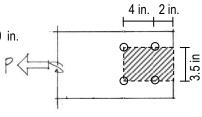

$$\phi(0.6F_yA_{gv} + U_{bs}F_vA_{nt}) = 0.75 \text{ x} (0.6 \text{ x} 36 \text{ ksi x} 3 \text{ in}^2 + 1 \text{ x} 58 \text{ ksi x} 1.25 \text{ in}^2) = 103.0 \text{ k}$$

The maximum connection capacity (*smallest value*) is governed by block shear rupture:

The steel used in the connection and beams is A992 with $F_y = 50$ ksi, and $F_u = 65$ ksi. Using A490-N bolt material, determine the maximum capacity of the connection based on shear in the bolts, bearing in all materials and pick the number of bolts and angle length (not staggered). Use A36 steel for the angles.

W21x93: d=21.62 in, $t_{\rm w}=0.58$ in, $t_{\rm f}=0.93$ in

W10x54: $t_f = 0.615$ in

TOP & BOTTOM BEAM W2|x92 COLUMN W10x54

SOLUTION:

The maximum length the angles can be depends on how it fits between the top and bottom flange with some clearance allowed for the fillet to the flange, and getting an air wrench in to tighten the bolts. This example uses 1" of clearance:

Available length = beam depth - both flange thicknesses - 1" clearance at top & 1" at bottom

$$= 21.62 \text{ in} - 2(0.93 \text{ in}) - 2(1 \text{ in}) = 17.76 \text{ in}.$$

With the spaced at 3 in. and 1 1/4 in. end lengths (each end), the maximum number of bolts can be determined:

Available length ≥ 1.25 in. + 1.25 in. + 3 in. x (number of bolts – 1)

number of bolts \leq (17.76 in - 2.5 in. - (-3 in.))/3 in. = 6.1, so 6 bolts.

It is helpful to have the All-bolted Double-Angle Connection Tables 10-1. They are available for ¾", 7/8", and 1" bolt diameters and list angle thicknesses of ¼", 5/16", 3/8", and ½". Increasing the angle thickness is likely to increase the angle strength, although the limit states include shear yielding of the angles, shear rupture of the angles, and block shear rupture of the angles.

For these diameters, the available **shear** (double) from Table 7-1 for 6 bolts is (6)45.1 k/bolt = 270.6 kips, (6)61.3 k/bolt = 367.8 kips, and (6)80.1 k/bolt = 480.6 kips.

Tables 10-1 (not all provided here) list a bolt and angle available strength of 271 kips for the ¾" bolts, 296 kips for the 7/8" bolts, and 281 kips for the 1" bolts. It appears that increasing the bolt diameter to 1" will not gain additional load. <u>Use 7/8" bolts.</u>

 $\phi R_n = 367.8$ kips for double shear of 7/8" bolts

 $\phi R_n = 296$ kips for limit state in angles

We also need to evaluate **bearing** of bolts on the beam web, and column flange where there are bolt holes. Table 7-4 provides available bearing strength for the material type, bolt diameter, hole type, and spacing per inch of material thicknesses.

a) Bearing for beam web: There are 6 bolt holes through the beam web. This is typically the critical bearing limit value because there are two angle legs that resist bolt bearing and twice as many bolt holes to the column. The material is A992 (F_u = 65 ksi), 0.58" thick, with 7/8" bolt diameters at 3 in. spacing.

 $\phi R_n = 6 \text{ bolts} \cdot (102 \text{ k/bolt/inch}) \cdot (0.58 \text{ in}) = 355.0 \text{ kips}$

b) Bearing for column flange: There are 12 bolt holes through the column. The material is A992 (F_u = 65 ksi), 0.615" thick, with 1" bolt diameters.

 $\phi R_n = 12 \text{ bolts} \cdot (102 \text{ k/bolt/inch}) \cdot (0.615 \text{ in}) = 752.8 \text{ kips}$

Although, the bearing in the beam web is the smallest at 355 kips, with the shear on the bolts even smaller at 324.6 kips, the maximum capacity for the simple-shear connector is 296 kips limited by the critical capacity of the angles.
