# Wood Design

## Notation:

| а | = name for width dimension |
|---|----------------------------|
|   | -                          |

A = name for area

- $A_{req'd-adj}$  = area required at allowable stress when shear is adjusted to include self weight
- b =width of a rectangle
  - = name for height dimension
- c = largest distance from the neutral axis to the top or bottom edge of a beam
  - = constant in  $C_p$  expression
- $c_1$  = coefficient for shear stress for a rectangular bar in torsion
- $C_D$  = load duration factor
- $C_{fu}$  = flat use factor for other than decks
- $C_F$  = size factor
- $C_H$  = shear stress factor
- $C_i$  = incising factor
- $C_L$  = beam stability factor
- $C_M$  = wet service factor
- $C_p$  = column stability factor for wood design
- $C_r$  = repetitive member factor for wood design
- $C_V$  = volume factor for glue laminated timber design
- $C_t$  = temperature factor for wood design
- d = name for depth
  - = calculus symbol for differentiation
- $d_{min}$  = dimension of timber critical for buckling
- D = shorthand for dead load = name for diameter
- DL = shorthand for dead load
- E = modulus of elasticity
- f = stress (strength is a stress limit)
- $f_b$  = bending stress
- $f_c$  = compressive stress
- $f_{from \ table} =$ tabular strength (from table)
- $f_p$  = bearing stress
- $f_v$  = shear stress
- $f_{v-max}$  = maximum shear stress
- $F_{allow}$  = allowable stress
- $F_b$  = tabular bending strength
  - = allowable bending stress

- $F'_b$  = allowable bending stress (adjusted)  $F_c$  = tabular compression strength parallel to the grain
- $F'_c$  = allowable compressive stress (adjusted)
- $F_{c}^{*}$  intermediate compressive stress for dependant on load duration
- $F_{cE}$  = theoretical allowed buckling stress
- $F_{c\perp}$  = tabular compression strength perpendicular to the grain
- $F_{connector}$  = shear force capacity per connector
- $F_p$  = tabular bearing strength parallel to the grain
  - = allowable bearing stress
- $F_t$  = tabular tensile strength
- $F_u$  = ultimate strength
- $F_v$  = tabular bending strength
  - = allowable shear stress
- h =height of a rectangle
- *I* = moment of inertia with respect to neutral axis bending
- $I_{trial}$  = moment of inertia of trial section
- $I_{req'd}$  = moment of inertia required at limiting deflection
- $I_y$  = moment of inertia about the y axis
- J =polar moment of inertia
- K = effective length factor for columns
- $K_{cE}$  = material factor for wood column design
- L = name for length or span length
- $L_e$  = effective length that can buckle for column design, as is  $\ell_e$
- LL = shorthand for live load
- LRFD = load and resistance factor design
- M = internal bending moment
- $M_{max}$  = maximum internal bending moment
- $M_{max-adj}$  = maximum bending moment adjusted to include self weight
- n =number of connectors across a joint, as is N
- p = pitch of connector spacing
  - = safe connector load parallel to the grain

| P = name for axial force vector                     | w = name for distributed load                       |
|-----------------------------------------------------|-----------------------------------------------------|
| $P_{allowable}$ = allowable axial force             | $w_{equivalent}$ = equivalent distributed load to   |
| q = safe connector load perpendicular               | produce the maximum moment                          |
| to the grain                                        | $w_{self wt}$ = name for distributed load from self |
| $Q_{connected} =$ first moment area about a neutral | weight of member                                    |
| axis for the connected part                         | x = horizontal distance                             |
| r = radius of gyration                              | y = vertical distance                               |
| R = radius of curvature of a deformed               | Z = force capacity of a connector                   |
| beam                                                | $\Delta_{actual}$ = actual beam deflection          |
| S = section modulus                                 | $\Delta_{allowable}$ = allowable beam deflection    |
| $S_{reg'd}$ = section modulus required at           | $\Delta_{limit}$ = allowable beam deflection limit  |
| allowable stress                                    | $\Delta_{max}$ = maximum beam deflection            |
| $S_{req'd-adj}$ = section modulus required at       | $\phi$ = resistance factor for LRFD                 |
| allowable stress when moment is                     | $\gamma$ = density or unit weight                   |
| $T_{\rm max}$ = torque (avial moment)               | $\theta$ = slope of the beam deflection curve       |
| I = torque (axial moment)                           | $\rho$ = radial distance                            |
| V = internal shear force                            |                                                     |
| $V_{max}$ = maximum internal shear force            | J = symbol for integration                          |
| $V_{max-adj}$ = maximum internal shear force        | $\Sigma$ = summation symbol                         |
| adjusted to include self weight                     |                                                     |

## Wood or Timber Design

Structural design standards for wood are established by the *National Design Specification (NDS)* published by the National Forest Products Association. There is a combined specification (from 2005) for **Allowable** Stress Design and limit state design (LRFD).

Tabulated wood strength values are used as the base allowable strength and modified by appropriate **adjustment** factors: f = C C C C + f

$$f = C_D C_M C_F \dots \times f_{from table}$$

#### Size and Use Categories

| Boards:          | 1 to $1\frac{1}{2}$ in. thick | 2 in. and wider |
|------------------|-------------------------------|-----------------|
| Dimension lumber | 2 to 4 in. thick              | 2 in. and wider |
| Timbers          | 5 in. and thicker             | 5 in. and wider |

## Adjustment Factors (partial list)

| C <sub>D</sub> load duration facto |
|------------------------------------|
|------------------------------------|

- C<sub>M</sub> wet service factor
  - (1.0 dry < 16% moisture content)
- $C_F$  size factor for visually graded sawn lumber and round timber > 12" depth

$$C_F = (12/d)^{\frac{1}{9}} \le 1.0$$

- C<sub>fu</sub> flat use factor (excluding decking)
- C<sub>i</sub> incising factor (from increasing the depth of pressure treatment)
- C<sub>t</sub> temperature factor (at high temperatures **strength** decreases)
- C<sub>r</sub> repetitive member factor
- C<sub>H</sub> shear stress factor (amount of splitting)
- $C_V$  volume factor for glued laminated timber (similar to  $C_F$ )
- C<sub>L</sub> beam stability factor (for beams without full lateral support)

#### Tabular Design Values

- $F_{h}$ : bending stress
- F<sub>t</sub>: tensile stress
- F<sub>v</sub>: horizontal shear stress
- $F_{c\perp}$ : compression stress (perpendicular to grain)
- F<sub>c</sub>: compression stress (parallel to grain)
- E: modulus of elasticity
- F<sub>p</sub>: bearing stress (parallel to grain)

Wood is significantly weakest in **shear** and strongest along the direction of the grain (tension and compression).

#### Load Combinations and Deflection

The critical load combination (ASD) is determined by the largest of either:

$$\frac{\text{dead load}}{0.9} \text{ or } \frac{(\text{ dead load + any combination of live load })}{C_D}$$

The deflection limits may be increased for less stiffness with total load: LL + 0.5(DL)

#### **Criteria for Design of Beams**

Allowable normal stress or normal stress from LRFD should not be  $F'_b \text{ or } \phi F_u \ge f_b = \frac{Mc}{I}$ exceeded:

Knowing M and F'<sub>b</sub>, the minimum section modulus fitting the limit is:

$$S_{req'd} \ge \frac{M}{F_b'}$$

Besides strength, we also need to be concerned about *serviceability*. This involves things like limiting deflections & cracking, controlling noise and vibrations, preventing excessive settlements of foundations and durability. When we know about a beam section and its material, we can determine beam deformations.

## Determining Maximum Bending Moment

Drawing V and M diagrams will show us the maximum values for design. Remember:

$$V = \Sigma(-w)dx$$
  

$$M = \Sigma(V)dx$$
  

$$\frac{dV}{dx} = -w$$
  

$$\frac{dM}{dx} = V$$

## Determining Maximum Bending Stress

For a prismatic member (constant cross section), the maximum normal stress will occur at the maximum moment.

For a non-prismatic member, the stress varies with the cross section AND the moment.

#### Deflections

If the bending moment changes, M(x) across a beam of constant material and cross section then the curvature will change:

The slope of the n.a. of a beam,  $\theta$ , will be tangent to the radius of curvature, R:  $\frac{1}{R} = \frac{M(x)}{EI}$ 

$$\theta = slope = \frac{1}{EI} \int M(x) dx$$

The equation for deflection, y, along a beam is:

$$y = \frac{1}{EI} \int \theta dx = \frac{1}{EI} \iint M(x) dx$$

Elastic curve equations can be found in handbooks, textbooks, design manuals, etc...Computer programs can be used as well (like *Multiframe*).

Elastic curve equations can be **superpositioned** ONLY if the stresses are in the elastic range. *The deflected shape is roughly the same shape flipped as the bending moment diagram but is constrained by supports and geometry.* 

## **Boundary Conditions**

The boundary conditions are geometrical values that we know – slope or deflection – which may be restrained by supports or symmetry.

At Pins, Rollers, Fixed Supports: y = 0

At Fixed Supports:  $\theta = 0$ 

At Inflection Points From Symmetry:  $\theta = 0$ 

The Slope Is Zero At The Maximum Deflection y<sub>max</sub>:

$$\theta = \frac{dy}{dx} = slope = 0$$

Allowable Deflection Limits

All building codes and design codes limit deflection for beam types and damage that could happen based on service condition and severity.

| Use                         | LL only  | DL+LL |
|-----------------------------|----------|-------|
| Roof beams:                 |          |       |
| Industrial                  | L/180    | L/120 |
| Commercial                  |          |       |
| plaster ceiling             | L/240    | L/180 |
| no plaster                  | L/360    | L/240 |
| Floor beams:                |          |       |
| Ordinary Usage              | L/360    | L/240 |
| Roof or floor (damageable e | lements) | L/480 |

With compression stresses in the top of a beam, a sudden "popping" or **buckling** can happen even at low stresses. In order to prevent it, we need to brace it along the top, or laterally brace it, or provide a bigger  $I_y$ .

## Beam Loads & Load Tracing

In order to determine the loads on a beam (or girder, joist, column, frame, foundation...) we can start at the top of a structure and determine the *tributary area* that a load acts over and the beam needs to support. Loads come from material weights, people, and the environment. This area is assumed to be from half the distance to the next beam over to halfway to the next beam.

The reactions must be supported by the next lower structural element *ad infinitum*, to the ground.

#### **Design** Procedure

The intent is to find the most light weight member satisfying the section modulus size.

- 1. Know  $F_{all}$  (F'<sub>b</sub>) for the material or  $F_U$  for LRFD.
- 2. Draw V & M, finding M<sub>max</sub>.
- 3. Calculate  $S_{req'd}$ . This step is equivalent to determining  $f_b = \frac{M_{max}}{C} \leq F_b'$
- 4. For rectangular beams  $S = \frac{bh^2}{c}$ 
  - For timber: use the section charts to find S that will work and remember that the beam  $W_{self wt} = \gamma A$ self weight will increase S<sub>rea'd</sub>.

\*\*\*\*Determine the "updated"  $V_{max}$  and  $M_{max}$  including the beam self weight, and verify that the updated S<sub>rea'd</sub> has been met. \*\*\*\*\*

- 5. Consider lateral stability.
- 6. Evaluate horizontal shear stresses using V<sub>max</sub> to determine if  $f_v \leq F'_v$  or find A<sub>req'd</sub>
- $f_{v-max} = \frac{3V}{2A} = 1.5 \frac{V}{A} \qquad \therefore A_{req'd} \le \frac{3V}{2F'_{\star}}$ For rectangular beams  $f_p = \frac{P}{A} \leq F'_p (from F_c \text{ or } F_{c\perp})$ 7. Provide adequate bearing area at supports:
- $f_v = \frac{T\rho}{J} or \frac{T}{c.ab^2} \le F'_v$ 8. Evaluate shear due to torsion

(circular section or rectangular)

9. Evaluate the deflection to determine if  $\Delta_{maxLL} \leq \Delta_{LL-allowed}$  and/or  $\Delta_{maxTotal} \leq \Delta_{Total-allowed}$ \*\*\*\* note: when  $\Delta_{calculated} > \Delta_{limit}$ ,  $I_{required}$  can be found with: and  $S_{req'd}$  will be satisfied for similar self weight \*\*\*\*\*  $I_{req'd} \ge \frac{\Delta_{loobig}}{\Delta_{limit}} I_{trial}$ 

#### FOR ANY EVALUATION:

Redesign (with a new section) at any point that a stress or serviceability criteria is NOT satisfied and re-evaluate each condition until it is satisfactory.

#### Load Tables for Uniformly Loaded Joists & Rafters

Tables exists for the common loading situation for joists and rafters – that of uniformly distributed load. The tables either provide the safe distributed load based on bending and deflection limits, they give the allowable span for specific live and dead  $M_{max} = \frac{W_{equivalent}L^2}{2}$ loads. If the load is not uniform, an equivalent distributed load can be calculated from the maximum moment equation.

If the deflection limit is less, the design live load to check against allowable must be increased, ex.

$$w_{adjusted} = w_{ll-have} \left(\frac{L/400}{L/360}\right)^{wanted}$$
 table limit

## Decking

Flat panels or planks that span several joists or evenly spaced support behave as continuous beams. Design tables consider a "1 unit" wide strip across the supports and determine maximum bending moment and deflections in order to provide allowable loads depending on the depth of the material.

The other structural use of decking is to construct what is called a *diaphragm*, which is a horizontal or vertical (if the panels are used in a shear wall) unit tying the sheathing to the joists or studs that resists forces parallel to the surface of the diaphragm.

## **Criteria for Design of Columns**

If we know the loads, we can select a section that is adequate for strength & buckling.

If we know the length, we can find the limiting load satisfying strength & buckling.

Any slenderness ratio,  $L_e/d \le 50$ :

$$f_{c} = \frac{P}{A} \le F_{c}' \qquad F_{c}' = F_{c}(C_{D})(C_{M})(C_{t})(C_{F})(C_{P})$$

The allowable stress equation uses factors to replicate the combination crushing-buckling curve:

where:

 $\begin{aligned} F_{c} &= \text{allowable compressive stress parallel to the grain} \\ F_{c} &= \text{compressive strength parallel to the grain} \\ c &= 0.8 \text{ for sawn lumber, } 0.85 \text{ for poles, } 0.9 \text{ for glulam timber} \\ C_{D} &= \text{load duration factor} \\ C_{M} &= \text{wet service factor (1.0 for dry)} \\ C_{t} &= \text{temperature factor} \\ C_{F} &= \text{size factor} \\ C_{p} &= \text{column stability factor off chart} \\ \text{or equation:} \\ \end{aligned}$ 

$$C_{p} = \frac{1 + (F_{cE} / F_{c}^{*})}{2c} - \sqrt{\left[\frac{1 + F_{cE} / F_{c}^{*}}{2c}\right]^{2} - \frac{F_{cE} / F_{c}^{*}}{c}}$$

For preliminary column design:

$$F_c' = F_c^* C_p = (F_c C_D) C_p$$

#### Procedure for Analysis

- 1. Calculate L<sub>e</sub>/d<sub>min</sub> (KL/d for each axis and chose largest)
- 2. Obtain F'<sub>c</sub>

compute 
$$F_{cE} = \frac{K_{cE}E}{\binom{l_e}{d}^2}$$
 or  $\frac{0.822E'_{\min}}{\binom{L_e}{d}^2}$  with  $K_{cE} = 0.3$  for sawn, = 0.418 for glu-lam

- 3. Compute  $F_c^* \cong F_c C_D$  with  $C_D = 1$ , normal,  $C_D = 1.25$  for 7 day roof...
- 4. Calculate  $F_{cE}/F_c^*$  and get C<sub>p</sub> from table or calculation
- 5. Calculate  $F_c' = F_c^* C_p$
- 6. Compute  $P_{allowable} = F'_c \cdot A$  or alternatively compute  $f_{actual} = P/A$
- 7. Is the design satisfactory?

Is  $P \le P_{allowable}$ ?  $\Rightarrow$  yes, it is; no, it is no good

or Is  $f_{actual} \leq F'_c$ ?  $\Rightarrow$  yes, it is; no, it is no good

#### Procedure for Design

- 1. Guess a size by picking a section
- 2. Calculate L<sub>e</sub>/d<sub>min</sub> (KL/d for each axis and chose largest)
- 3. Obtain F'<sub>c</sub>

compute 
$$F_{cE} = \frac{K_{cE}E}{\binom{l_e}{d}^2}$$
 or  $\frac{0.822E'_{min}}{\binom{L_e}{d}^2}$  with  $K_{cE} = 0.3$  for sawn, = 0.418 for glu-lam

- 4. Compute  $F_c^* \cong F_c C_D$  with  $C_D = 1$ , normal,  $C_D = 1.25$  for 7 day roof...
- 5. Calculate  $F_{cE}/F_c^*$  and get C<sub>p</sub> from table or calculation
- 6. Calculate  $F_c' = F_c^* C_p$
- 7. Compute  $P_{allowable} = F'_{c} \cdot A$  or alternatively compute  $f_{actual} = P/A$
- 8. Is the design satisfactory?

Is  $P \le P_{allowable}$ ?  $\Rightarrow$  yes, it is; no, pick a bigger section and go back to step 2. or Is  $f_{actual} \le F'_c$ ?  $\Rightarrow$  yes, it is; no, pick a bigger section and go back to step 2.

## Columns with Bending (Beam-Columns)

The modification factors are included in the form: where:

$$\left[\frac{f_{c}}{F_{c}'}\right]^{2} + \frac{f_{bx}}{F_{bx}' \left[1 - \frac{f_{c}}{F_{cEx}}\right]} \le 1.0$$

$$1 - \frac{f_c}{F_{cEx}}$$
 = magnification factor accounting for P- $\Delta$   
 $F'_{bx}$  = allowable bending stress

 $f_{bx}$  = working stress from bending about x-x axis

In order to *design* an adequate section for allowable stress, we have to start somewhere:

- 1. Make assumptions about the limiting stress from:
  - buckling
  - axial stress
  - combined stress
- 2. See if we can find values for <u>r</u> or <u>A</u> or <u>S (=I/c<sub>max</sub>)</u>
- 3. Pick a trial section based on if we think r or A is going to govern the section size.
- 4. Analyze the stresses and compare to allowable using the allowable stress method or interaction formula for eccentric columns.
- 5. Did the section pass the stress test?
  - If not, do you *increase* r or A or S?
  - If so, is the difference really big so that you could *decrease* r or A or S to make it more efficient (economical)?
- 6. Change the section choice and go back to step 4. Repeat until the section meets the stress criteria.

## **Criteria for Design of Connections**

Connections for wood are typically mechanical fasteners. Shear plates and split ring connectors are common in trusses. Bolts of metal bear on holes in wood, and nails rely on shear resistance transverse and parallel to the nail shaft. Timber rivets with steel side plates are allowed with glue laminated timber.

Connections must be able to transfer any axial force, shear, or moment from member to member or from beam to column.

#### **Bolted Joints**

Stress must be evaluated in the member being connected using the load being transferred and the reduced cross section area called *net area*. Bolt capacities are usually provided in tables and take into account the allowable shearing stress across the diameter for *single* and *double shear*, and the allowable bearing stress of the connected material based on the direction of the load with

respect to the grain. Problems, such as ripping of the bolt hole at the end of the member, are avoided by following code guidelines on minimum edge distances and spacing.

#### Nailed Joints

Because nails rely on shear resistance, a common problem when nailing is splitting of the wood at the end of the member, which is a shear failure. Tables list the shear force capacity per unit length of embedment per nail. Jointed members used for beams will have shear stress across the connector, and the pitch spacing, p, can be determined from the shear stress equation when the capacity, F, is known:

$$nF_{connector} \ge \frac{VQ_{connected area}}{I} \cdot p$$

#### Example 1 (pg 204)

**Example 2.** A simple beam has a span of 16 ft [4.88 m] and supports a total uniformly distributed load, including its own weight, of 6500 lb [28.9 kN]. Using Douglas fir-larch, select structural grade, determine the size of the beam with the least cross-sectional area on the basis of limiting bending stress. Density of douglas fir-larch is 32 lb/ft<sup>3</sup>

Example 2 (pg 207)

*Example 3.* A  $6 \times 10$  beam of Douglas fir-larch, No. 2 grade, has a total horizontally distributed load of 6000 lb [26.7 kN]. Investigate for shear stress.

Example 3 (pg 209)

**Example 6.** A two-span  $3 \times 12$  beam of Douglas fir-larch, No. 1 grade, bears on a  $3 \times 14$  beam at its center support. If the reaction force is 4200 lb [18.7 kN], is this safe for bearing?

#### Example 4 (pg 212)

**Example 7.** An  $8 \times 12$  wood beam with E = 1,600,000 psi is used to carry a total uniformly distributed load of 10 kips on a simple span of 16 ft. Find the maximum deflection of the beam.

#### Example 5 (pg 223)

*Example13.* Using Table 5.10 select joists to carry a live load of 40 psf and a dead load of 10 psf on a span of 15 ft 6 in. if the spacing is 16 in. on center.

|                             |                    | Jois            | t Size               |            |
|-----------------------------|--------------------|-----------------|----------------------|------------|
| Spacing (in.)               | 2 × 6              | 2 × 8           | $2 \times 10$        | 2 × 12     |
| Live load $= 40 \text{ ps}$ | f, Dead load $= 1$ | 0 psf, Maximum  | live-load deflection | pn = L/360 |
| 12                          | 10-9               | 14-2            | 17-9                 | 20-7       |
| 16                          | 9-9                | 12-7            | 15-5                 | 17-10      |
| 19.2                        | 9-1                | 11-6            | 14-1                 | 16-3       |
| 24                          | 8-1                | 10-3            | 12-7                 | 14-7       |
| Live load $= 40$ ps         | f, Dead load = 2   | 20 psf, Maximum | live-load deflection | on = L/360 |
| 12                          | 10-6               | 13-3            | 16-3                 | 18-10      |
| 16                          | 9-1                | 11-6            | 14-1                 | 16-3       |

<sup>a</sup> Joists are Douglas fir-larch, No. 2 grade. Assumed maximum available length of single piece is 26 ft.

#### Example 6

Design a Southern pine No. 1 beam to carry the loads shown (roof beam, no plaster). Assume the beam is supported at each end of by an 8" block wall.  $F_b = 1500$  psi;  $F_v = 110$  psi;  $F_{c\perp} = 440$  psi;  $E = 1.6 \times 10^6$  psi;  $\gamma = 36.3$  lb/ft<sup>3</sup>.

#### SOLUTION:

Because this beam appears to support other beams at the locations of the roof construction loads, we have to assume that this beam is not closely spaced to others and the repetitive use adjustment factor doesn't apply. The load duration factor,  $C_D$ , is 1.25 for roof construction loads. The other conditions (like temperature and moisture) must be assumed to be normal (and have values of 1.0). The allowable stresses can be determined from:

$$F'_{b} = C_D F_b = (1.25)(1500) = 1875 \text{ psi}$$
  
 $F'_{v} = C_D F_v = (1.25)(110) = 137.5 \text{ psi}$   
 $F'_{c\perp} = C_D F_{c\perp} = (1.25)(440) = 550 \text{ psi}$ 

Bending:

$$S_{req'd} \ge \frac{M}{F_b'} = \frac{12,813^{lb-ft}(12^{in}/ft)}{1875\,psi} = 82.0in^3$$

Shear:

$$A_{req'd} \ge \frac{3V}{2F_v'} = \frac{3(2,750lb)}{2(137.5psi)} = 30.0in^2$$

Try a 3 x 16. This satisfies both requirements with the least amount of area. (See the 4 x 14, 6 x 10, and 8 x 10.)

$$(A = 38.13 \text{ in}^2, S = 96.90 \text{ in}^3, I_x = 738.9 \text{ in}^4)$$

$$w_{self wt.} = \gamma A = \frac{\frac{36.3 \frac{lb}{ft^3} (38.13in^2)}{(12\frac{in}{ft})^2} = 9.61\frac{lb}{ft} \text{ which is } \underline{additional} \text{ dead load!}$$

Because the maximum moment from the additional distributed load is at the same location as the maximum moment from the diagram, we can add them:

$$M_{adjusted} = 12,813^{lb-ft} + \frac{9.61^{lb}/_{ft}(15ft)^2}{8} = 13,083.3^{lb-ft} \text{ and } S^*_{req'd} \ge \frac{13,083.3^{lb-ft}(12^{in}/_{ft})}{1875\,psi} = 83.7in^3$$

The same holds true for the contribution to the shear:

$$V_{adjusted} = 2,750lb + \frac{9.61^{b/ft}(15ft)}{2} = 2822.1lb$$
 and  $A_{req'd}^{*} \ge \frac{3(2822.1lb)}{2(137.5psi)} = 30.79in^{2}$ 

Check that the section chosen satisfies the new required section modulus and area:

| Is Sthat I have $\geq$ Sthat I <u>need</u> ?             | Is 96.90 in <sup>3</sup> ≥ 83.7 in <sup>3</sup> ?      | Yes, OK. |
|----------------------------------------------------------|--------------------------------------------------------|----------|
| Is $A_{\text{that I have}} \ge A_{\text{that I need}}$ ? | Is 38.13 in <sup>2</sup> $\ge$ 30.79 in <sup>2</sup> ? | Yes, OK. |

NOTE: If the area or section that I have is not adequate, I need to choose one that is. This will have a **larger** self weight that must be determined and included in the maximum moment (with the initial maximum). It will make  $S^*_{reqd}$  and  $A^*_{reqd}$  bigger as well, and the new section properties must be evaluated with respect to these new values.

#### Deflection:

The total deflection due to dead and live loads must not exceed a limit specified by the building code adopted (for example, the *International Building Code*) or recommended by construction manuals. For a commercial roof beam with no plaster, the usual limits are L/360 for *live load only* and L/240 for *live and dead load*.

$$\Delta_{LL-limit} = \frac{15 ft(12^{in}/ft)}{360} = 0.5 in \qquad \Delta_{total-limit} = \frac{15 ft(12^{in}/ft)}{240} = 0.75 in$$

<u>Superpositioning</u> (combining or superimposing) of several load conditions can be performed, but **care must be taken** that the deflections calculated for the separate cases to obtain the maximum **must be deflections at the same location** in order to be added together:

two symmetrically placed equal point loads (live load): (a is the distance from the supports to the loads)

$$\Delta_{max}(at \ center \ ) = \frac{Pa}{24EI}(3l^2 - 4a^2) = \frac{2000lb(5ft)}{24(1.6x10^6 \ psi)(738.9in^4)}(3(15ft)^2 - 4(5ft)^2)(12in/_{ft})^3 = 0.35in$$

distributed load (dead load)

 $\Delta_{max}(at center) = \frac{5wl^4}{384EI} = \frac{5(100 + 9.61^{lb}/_{ft})(15ft)^4(12i'/_{ft})^3}{384(1.6x10^6 psi)(738.9in^4)} = 0.11in$ 

| Is $\Delta_{	ext{live that I have}} \leq \Delta_{	ext{live-limit}}?$      | Is 0.35 in $\leq$ 0.5 in?                       | Yes, OK. |
|---------------------------------------------------------------------------|-------------------------------------------------|----------|
| Is $\Delta_{	ext{total}}$ that I have $\leq \Delta_{	ext{total-limit}}$ ? | Is (0.35 in + 0.11 in) = 0.46 in $\le$ 0.75 in? | Yes, OK. |

Bearing:

Determine if the bearing stress between the beam and the block wall support less than the allowable. If it is not, the beam width must be increased:

$$f_p = \frac{P}{A} = \frac{2822.1b}{(2.5in)(8in)} = 141.1psi \le F'_{c\perp} = 550 psi$$
 so, yes the beam width (2.5 in) is adequate.

USE a 3 x 16.

#### Example 7 (pg 239)

**Example 1.** A wood column consists of a  $6 \times 6$  of Douglas fir-larch, No. 1 grade. Find the safe axial compression load for unbraced lengths of: (1) 2 ft, (2) 8 ft, (3) 16 ft. using the ASD method.

Example 8

#### Example Problem 10.18 (Figures 10.60 and 10.61)

An 18' tall 6×8 Southern pine column supports a roof load (dead load plus a 7-day live load) equal to 16 kips. The weak axis of buckling is braced at a point 9'6" from the bottom support. Determine the adequacy of the column.

 $F_c = 975 \text{ psi}, E = 1.6 \times 10^6 \text{ psi}$ 

#### Example 8 (fully worked)

#### Example Problem 10.18 (Figures 10.60 and 10.61)

An 18' tall 6×8 Southern pine column supports a roof load (dead load plus a 7-day live load) equal to 16 kips. The weak axis of buckling is braced at a point 9'6" from the bottom support. Determine the adequacy of the column.

#### Solution:

6×8 S4S Southern pine post: ( $A = 41.25 \text{ in.}^2$ ,  $F_c = 975 \text{ psi}$ ,  $E = 1.6 \times 10^6 \text{ psi}$ )

Check the slenderness ratio about the weak axis:

$$\frac{L_e}{d} = \frac{(9.5' \times 12 \text{ in./ft.})}{5.5''} = 20.7$$

The slenderness ratio about the strong axis is:

$$\frac{L_e}{d} = \frac{(18' \times 12 \text{ in./ft.})}{7.5''} = 28.8 \leftarrow \text{governs}$$

$$F_{cE} = \frac{0.3E}{(L_e/d)^2} = \frac{0.3 (1.6 \times 10^6 \text{ lb./in.}^2)}{(28.8)^2} = 579 \text{ psi}$$

$$F_c^* \cong F_c C_D = (975 \text{ lb./in.}^2)(1.25) = 1220 \text{ psi}$$
where:  $C_D = 1.25$  for 7-day-duration load  $\frac{F_{cE}}{F_c} = \frac{579 \text{ psi}}{1220 \text{ psi}}$ 
From Appendix Table 14:  $C_p = 0.412$ 

$$\therefore F'_c = F^*_c C_p = 1220 \text{ lb./in.}^2 \times 0.412 = 503 \text{ psi}$$

$$P_a = F'_c \times A = (503 \text{ lb./in.}^2) \times (41.25 \text{ in.}^2)$$

$$= 20,700 \text{ lb.}$$

$$P_a = 20.7 \text{ k} > P_{\text{actual}} = 16 \text{ k}$$

The column is adequate.

Figure 10.60 Wood column with intermediate bracing.

Figure 10.61 (a) Strong axis. (b) Weak axis.

## Example 9 (pg 251)

**Example** 4. An exterior wall stud of Douglas fir-larch, stud grade, is loaded as shown in Figure 6.5*a*. Investigate the stud for the combined loading. (*Note:* This is the wall stud from the building example in Chapter 18.) (*Wind load duration does apply, as well as load combinations.*)

<sup>1</sup>Tabulated values are on a normal load-duration basis and apply to joints made of seasoned lumber used in dry locations. See Division III for other service conditions.

<sup>2</sup>Double shear values are for joints consisting of three wood members in which the side members are one half the thickness of the main member. Single shear values are for joints consisting of two wood members having a minimum thickness not less than that specified.

<sup>3</sup>See Division III for wood-to-metal bolted joints.

<sup>4</sup>The length specified is the length of the bolt in the main member of double shear joints or the length of the bolt in the thinner member of single shear joints.
