# **Case Study in Timber**

adapted from Simplified Design of Wood Structures, James Ambrose, 5<sup>th</sup> ed.

# **Building description**

The building is a one-story building intended for commercial occupancy. Figure 16.1 presents a building plan, partial elevation, section and elevation of the perimeter shear walls. Light wood framing (assuming the fire resistance requirements have been met) will be used.

#### Loads

Live Loads:

Roof: 20 lb/ft<sup>2</sup> (0.96 kPa)

*Wind:* critical at 20 lb/ft<sup>2</sup> (0.96 kPa) on vertical exterior surfaces.

#### Dead Loads:

Roofing & deck: 7.5 lb/ft<sup>2</sup> (0.36 kPa) Ceiling joists, ceiling & fixtures: 6.5 lb/ft<sup>2</sup> (0.31 kPa)

Total: 14 lb/ft<sup>2</sup> (0.67 kPa)

# 3' [0.9m] 2.5' [0.75m] 6" 20' [0.15m] [6m] (c) Section

#### Materials

Wood framing of Douglas fir-larch, structural grades No. 1 & 2 having a density of 32 lb/ft<sup>3</sup>, and AITC glulam timber.

Figure 16.1 Building One, general form.

#### Structural Elements/Plan

If the interior partition walls are arranged as in Figure 16.3a, there are options on the arrangement of the roof structure. We will analyze case 16.3b consisting of roof deck and rafters, stud walls, continuous (two span) beams, and columns.

Figure 16.3 Developed plan for interior partitioning and alternatives for the roof framing.

## **Decking & Rafters:**

The standard size of plywood or structural deck panel is 4 ft x 8 ft. The typical orientation is with the long direction with the face grain perpendicular to the rafters or floor joists. (See cross hatching in Figure 16.3.) Typical joist and rafter spacings are 12 in., 16 in., and 24 in. on center. If we use 16 in. on center, the total distributed roof loads (with allowable stress design) with an assumed self weight of 4 lb/ft is:

$$w = (20 \text{ lb/ft}^2 + 14 \text{ lb/ft}^2) \cdot 16 \text{ in/12 in/ft} + 4 \text{ lb/ft} = 49.3 \text{ lb/ft}$$

$$M_{\text{max}} = \frac{wL^2}{8} = \frac{49.3^{\frac{b}{ft}}(21^{ft})^2}{8} = 2718^{\frac{b-ft}{2}}$$

Tabular allowable stresses for No. 2 Douglas fir-larch, 2"-4" thick and 2" to 4" wide are:

$$F_{b-single} = 875^{psi}, F_{v} = 95^{psi}, F_{c\perp} = 625^{psi}, F_{c} = 1300^{psi}, E = 1,600,000^{psi}$$

The load duration for roof loads,  $C_D = 1.25$ . The repetitive member factor,  $C_r = 1.15$ , applies and the adjusted allowed stress for a fully braced 2x is:

$$F_b' = C_D C_r F_b = (1.25)(1.15)(875 \text{ psi}) = 1258 \text{ psi}$$

**SECTION PROPERTIES** 

The required section modulus is

$$S_{\text{req'd}} \ge \frac{M}{F_b'} = \frac{2718^{\text{lb}-\text{ft}} \cdot 12^{\text{in/ft}}}{1258^{\text{psi}}} = 25.9 \,\text{in}^3$$

A 2x12 will work if the deflection is limited to allowable for the building code. (This tends to govern for floors. Shear stress should also be checked).

#### **Continuous Beams:**

The distributed load, including an estimated self weight of 11 lb/ft (about a 6 in x 12 in section) of a glulam beam can be found from:

rafter distributed load:

$$\frac{\gamma \cdot A \cdot trib. \ width}{rafter \ spacing} = \frac{(32 \frac{lb}{ft^3})(16.88 in^2)(21 \frac{ft}{2} + 8 \frac{ft}{2})}{16 in} \cdot \left(\frac{1 ft}{12 in}\right)^2 \cdot \frac{12 in}{ft} = 40.8 \frac{lb}{ft}$$

roof load:

$$(20 \text{ lb/ft}^2 + 14 \text{ lb/ft}^2) \cdot (21 \text{ft/2} + 8 \text{ft/2}) = 493^{\text{ lb/ft}}$$

total distributed load:

$$w = 40.8 \text{ lb/ft} + 493 \text{ lb/ft} + 11 \text{ lb/ft} = 545 \text{ lb/ft}$$

The maximum positive moment is  $0.07 wL^2$  and the maximum negative moment over the support is  $0.125 wL^2$ , where L is the length of one span.  $V_{max} = 0.625 wL$ . (These values come from a beam diagram.)

$$M_{max} = 0.125(545 \text{ lb/ft})(16.67 \text{ ft})^2 = 18,931^{\text{lb-ft}}$$

$$V_{\text{max}} = 0.625(545 \text{ lb/ft})(16.67 \text{ ft}) = 5678 \text{ lb}$$

$$F_b' = C_D F_b = (1.25)(2400 \text{ psi}) = 3000 \text{ psi}$$

$$S_{req'd} \ge \frac{M}{F_b'} = \frac{18931^{lb-ft}}{3000^{psi}} \cdot 12^{in}/_{ft} = 75.7 \ in^3$$

From SECTION PROPERTIES/STANDARD SIZES, the 5  $\frac{1}{8}$  " x 10.5" is adequate, although a 3  $\frac{1}{8}$  " x 13.5" could be evaluated.

TABLE SPECIFICATIONS: This table applies to straight, simply supported glued laminated timber beams under dry

conditions of use. Beams must be laterally supported at the top along the length of the beam and at the top and bottom

at the ends. The load carrying capacities tabulated are for total load including the weight of the member.

BEAM WEIGHT: 35.0 pounds per cubic foot was used to determine beam weight per lineal foot shown in the table.

DESIGN VALUE MODIFICATIONS: The allowable stress in bending , Fb , has been adjusted by the AITC volume factor, CV .

For determination of load carrying capacities governed by shear, loads within a distance "d" (the depth of the beam) from the ends have been neglected. DEFLECTION LIMITS: For roof beams, deflection is limited to span /180 for total load.

CONTROLLING VALUES: Values marked with a D are controlled by deflection, B are bending controlled, and S are shear controlled.

SPAN: Span is defined as the length from centerline to centerline of bearing. This span is the length used in standard engineering equations to calculate deflection, bending and shear.

\* The values have been limited to reasonable capacities. Engineering calculations may allow for greater capacities.

Feb-2001

While these capacity tables have been prepared in accordance with recognized engineering principles and are based on the most accurate and reliable technical data available, these tables should not be used or relied upon for any general or specific application without competent professional examination and verification of their accuracy, suitability, and applicability by a licensed professional engineer, designer, or architect. AITC MAKES NO REPRESENTATION OR WARRANTY, EXPRESSED OR IMPLIED, THAT THE INFORMATION CONTAINED HEREIN IS SUITABLE FOR ANY GENERAL OR SPECIFIC USE OR IS FREE FROM INFRINGEMENT OF ANY PATENT OR COPYRIGHT. ANY USER OF THIS INFORMATION ASSUMES ALL RISK AND LIABILITY ARISING FROM SUCH USE.

The self weight should be determined to compare to the assumption. Table DF-25 indicates the self weight is 13 lb/ft, and that size at our span is controlled by deflection (I for  $\Delta$ =L/180), but this chart is for *simply supported beams* and  $\Delta_{\text{max}} = \frac{5wL^4}{384EI}$ .

The maximum deflection for a two span beam can be found with  $\Delta_{\text{max}} = \frac{wL^4}{185EI}$ , which is only 0.415x the deflection of a simply supported span.

For sawn lumber, a 6x14 would be required from the comparison chart.

Evaluate shear strength:

$$F'_v = C_D F_v = (1.25)240 \text{ psi} = 300 \text{ psi}$$

$$f_v = \frac{3V}{2A} = \frac{3(5678lb)}{2(53.8in^2)} = 158psi$$

which is less than the allowable of 300 psi (OK).

#### **Stud Walls & Columns:**

Building codes dictate the maximum height for slenderness (10 ft typical), and the spacing of wall studs depending on what they support (roof, roof and one floor, roof and two floors). Structural design focuses on shear wall behavior.

The interior column load is:

 $P = 1.25 \text{wL} = 1.25(545 \text{ lb/ft} + 2 \text{ lb/ft} \text{ of extra beam self weight})(16.67 \text{ ft}) = 11.4^{\text{kips}}$ 

For a 10 ft braced column height, choose a 6 x 6.

<sup>&</sup>lt;sup>a</sup>Load capacity in kips for solid-sawn sections of No. 1 grade Douglas fir-larch under normal moisture and load duration conditions.

# Wind Design:

Diaphragms are categorized as flexible or rigid and must resist lateral forces in both transverse and longitudinal directions. A diaphragm is made up of a shear-resisting element (sheathing) and boundary members called *chords* and *collectors* (*struts or drag struts*). The chords are designed to carry the moment in the diaphragm. The collectors are designed to transmit the horizontal reactions to the shear walls. The structural behavior is often compared to that of a steel I section on its side (Figure 15.6).

Figure 15.6 Flanged and webbed beam analogy for a horizontal, wood-framed diaphragm.

Tables in building codes for combinations of plywood grade, common nail size, plywood thickness, how the panels are arrayed and if blocking is used provide allowable shear in pounds per foot.

Consideration of lateral wind loads will be presented, but uplift on the roof must be accounted for with anchorage if the live load exceeds the downward gravity loads.

Selected Tables from the Uniform Building Code, 1997 Edition

<sup>&</sup>lt;sup>1</sup>These values are for short-time loads due to wind or earthquake and must be reduced 25 percent for normal loading. Space nails 12 inches (305 mm) on center along intermediate framing members.

Allowable shear values for nails in framing members of other species set forth in Division III, Part III, shall be calculated for all other grades by multiplying the shear capacities for nails in Structural I by the following factors: 0.82 for species with specific gravity greater than or equal to 0.42 but less than 0.49, and 0.65 for species with a specific gravity less than 0.42.

<sup>&</sup>lt;sup>2</sup>Framing at adjoining panel edges shall be 3-inch (76 mm) nominal or wider and nails shall be staggered where nails are spaced 2 inches (51 mm) or 2<sup>1</sup>/<sub>2</sub> inches (64 mm) on center.

<sup>&</sup>lt;sup>3</sup>Framing at adjoining panel edges shall be 3-inch (76 mm) nominal or wider and nails shall be staggered where 10d nails having penetration into framing of more than 1<sup>3</sup>/<sub>8</sub> inches (41 mm) are spaced 3 inches (76 mm) or less on center.

#### North-South

Figure 16.5 Building One, wall functions and wind pressure development.

The tributary height for the wall and parapet is 17.5 ft/2 + 2.5 ft = 11.25 ft

The distributed lateral wind load =  $(20 \text{ lb/ft}^2)11.25\text{ft} = 225 \text{ lb/ft}$ 

The total lateral wind load = (225 lb/ft)(100 ft) = 22,500 lb

The end reactions to the lateral load = 22,500 lb/2 = 11,250 lb

(a) Wall funcions for wind

The *unit shear* (or distributed shear) in the **diaphragm** = 11,250 lb/(50 ft) = 225 lb/ft;

so a roof deck can be chosen that has an allowable shear > 225 lb/ft.

Knowing that ½ in decking is the minimum for a membrane-type roof, we use table 23-II-H to select ½ in. sheathing with 2 x framing and 8d nails at 6 in. at all panel edges and a blocked diaphragm having an allowable shear in pounds per foot of 270 lb/ft.

The moment of the "deep beam" is used to determine the force in the top and bottom chords as show in Figure 16.6 which is 5.62 kips.

The *unit shear* in the two **shear walls** of 21 ft each = 11,250 lb/(2.21 ft) = 268 lb/ft;

so a stud wall can be chosen that has an allowable shear > 268 lb/ft.

Using table 23-II-I-1,  $\frac{3}{8}$  in. plywood sheathing with 6d nails at 4 in. at all panel edges directly applied to framing (not over gypsum sheathing) has an allowable shear in pounds per foot of 300 lb/ft.

Figure 16.6 Spanning functions of the roof diaphragm.

<sup>&</sup>lt;sup>1</sup>All panel edges backed with 2-inch (51 mm) nominal or wider framing. Panels installed either horizontally or vertically. Space nails at 6 inches (152 mm) on center along intermediate framing members for <sup>3</sup>/<sub>8</sub>-inch (9.5 mm) and <sup>7</sup>/<sub>16</sub>-inch (11 mm) panels installed on studs spaced 24 inches (610 mm) on center and 12 inches (305 mm) on center for other conditions and panel thicknesses. These values are for short-time loads due to wind or earthquake and must be reduced 25 percent

(305 mm) on center for other conditions and panel thicknesses. These values are for short-time loads due to wind or earthquake and must be reduced 25 percent for normal loading.

Allowable shear values for nails in framing members of other species set forth in Division III, Part III, shall be calculated for all other grades by multiplying the shear capacities for nails in Structural I by the following factors: 0.82 for species with specific gravity greater than or equal to 0.42 but less than 0.49, and 0.65 for species with a specific gravity less than 0.42.

Where panels are applied on both faces of a wall and nail spacing is less than 6 inches (152 mm) on center on either side, panel joints shall be offset to fall on different framing members or framing shall be 3-inch (76 mm) nominal or thicker and nails on each side shall be staggered.

3Where allowable shear values exceed 350 pounds per foot (5.11 N/mm), foundation sill plates and all framing members receiving edge nailing from abutting panels shall not be less than a single 3-inch (76 mm) nominal member. Nails shall be staggered.

4The values for <sup>3</sup>/<sub>8</sub>-inch (9.5 mm) and <sup>7</sup>/<sub>16</sub>-inch (11 mm) panels applied direct to framing may be increased to values shown for <sup>15</sup>/<sub>32</sub>-inch (12 mm) panels, provided studs are spaced a maximum of 16 inches (406 mm) on center or panels are applied with long dimension across studs.

5Galvanized nails shall be hot-dipped or tumbled.

Wall overturning must be considered from the shear and compared to the resisting moment from gravity loads and proper anchorage must be provided to keep the wall from sliding off the foundation. Referring to Figure 16.7:

$$V = 11.25 \text{ k/ } 2 = 5.625 \text{ k}$$

Roof dead load is determined from a tributary area of half a rafter spacing width, one rafter, and the wall length

$$roof DL = (14 \text{ lb/ft}^2 \cdot 16 \text{ in/12 in/ft/2} + 4 \text{ lb/ft}) \cdot 21 \text{ ft} = 280 \text{ lb}$$

Wall dead load can be determined with the material weights for stud walls, sheathing, gypsum board and wood shingles:

$$wall DL = (2 lb/ft^2 + 3 lb/ft^2 + 5 lb/ft^2 + 2 lb/ft^2) (21 ft)(17 ft) = 4.3 k$$

overturning 
$$moment = (5.625k)(17 \text{ ft}) = 95.6 \text{ k-ft}$$

resisting moment = 
$$(4.6 \text{ k})(21 \text{ ft})/2 = 48.4 \text{ k-ft}$$

The resisting moment is not enough to compensate for the overturning moment. We like the factor of safety for overturning to be 1.5, and there *is no safety* in this case, which means we must provide a tie down in tension (T). The L shape of the corner will help some resisting overturning, as well as the glulam beam reaction.

For equilibrium of moments (positive = negative)

$$SF = \frac{M_{resist}}{M_{overturning}} \ge 1.5$$

$$T(21ft) + 48.4 \text{ k-ft} = (95.6 \text{ k-ft})1.5;$$

$$T_{req'd} = 4.52 \ k$$

The shear must be resisted, and the code minimum bolting usually consists of ½ in. diameter bolts at 1 ft from the wall ends and at a maximum of 6 ft on center for the remainder of the wall length. If design for wind loading allows us to increase the allowable stress by 1/3, the number of bolts from single shear in a 2" sill plate parallel to the grain will be:

 $(1.33)(480 \text{ lb/bolt})(n) \ge 5,625 \text{ lb}$ 

 $n \ge 8.8$  bolts Use 9 bolts, spaced at 2.375 ft (see next page for description of design value symbols)

 $Z_{\parallel}$  = nominal lateral design value for single bolt in connection with all wood members loaded parallel to grain

 $Z_{s\perp}$  = nominal lateral design value for single bolt in wood-to-wood connection with main member loaded parallel to grain and side member loaded perpendicular to grain

 $Z_{m\perp}$  = nominal lateral design value for single bolt in wood-to-wood connection with main member loaded parallel to grain and side member loaded perpendicular to grain and side member loaded parallel to grain

## East-West

Figure 16.5 Building One, wall functions and wind pressure development.

The tributary height for the wall and parapet and the distributed lateral wind load are the same as in the North-South direction.

The total lateral wind load = (225 lb/ft)(50 ft) = 11,250 lb

The end reactions to the lateral load = 11,250 lb/2 = 5,625 lb

The *unit shear* (or distributed shear) in the **diaphragm** = 5,625 lb/(100 ft) = 56.25 lb/ft.

It is convenient to use the diaphragm structural panel construction chosen in the North-South direction with a capacity of 270 lb/ft.

The *unit shear* (or distributed shear) in the five **shear walls** of 10.67 ft each:

$$= 5,625 \text{ lb/}(5.10.67 \text{ ft}) = 105 \text{ lb/ft}.$$

It is convenient to use the shear wall structural panel construction chosen in the North-South direction with a capacity of 300 lb/ft.
